PRINTED AND PUBLISHED BY THE REGISTERED PROPRIETORS, AT THE OFFICES OF "THE LANCET," No. 423, STRAND, AND Nos. 1 & 2 BEDFORD STREET, STRAND.

MCMXI.

An Address
ON
TEMPERAMENTS: IS THERE A NEUROTIC ONE?

Being the Mid-sessional Address delivered before the Abernethian Society of St. Bartholomew's Hospital on June 8th, 1911,

BY ROBERT JONES, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

LECTURER ON MENTAL DISEASES, ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL; RESIDENT PHYSICIAN AND SUPERINTENDENT, LONDON COUNTY ASYLUM, CLAYBURY.

GENTLEMEN,—This is an age which concerns itself about "equality of opportunity" if not "equality" in many other directions. Democracy, represented by the State, insists that there should be no privileged class, that every person has a right to decent education, housing and food, and that the net for preferment, promotion, and office should be cast widely; but there are drawbacks to this Utopian scheme. We are not all constituted alike, and to avoid waste of energy on the part of the State to bring about equality, as well as on the part of the individual to be equalised, it is well we should know the "square pegs," "misfits," and even "impossibles"! We know people as tall or short, fair or dark, square or slim, and we know by experience that "one man's meat is another's poison," and if we can discover by some special means of observation the distribution of endowment, the capacity for education, the suitability for occupation, the fitness for after life, the taste, the disposition or tendency to act, or even the susceptibility to disease, in other words, if we can ascertain the "temperament" of the individual, we and he, or she, may be saved much disappointment and sorrow, possibly also of misery and shame.

In medicine we know that drugs act differently on different persons, and sometimes the normal effect fails to appear unless the dose is varied. Some cannot take quinine, others are affected unphysiologically by opium. One person becomes insufferably ill from the presence of a cat in the room, another at the odour of lilies. One suffers emotional disturbance at the creaking of new boots, another when a pencil writes on a slate, a third at the creasing of paper or the scraping of finger-nails, and similar personal idiosyncrasies have disturbed men of great mental power and ability. Schiller required the odour of decaying apples to stimulate him in composition, and Kant the sight of a button on a student's coat to help him to lecture, and I have known promising adolescents in my own profession who could work better when a photograph of their admired one was on their study table! We know the course of disease in different persons necessitates different treatment, we have learnt that different climates have to be avoided by different people—one cannot live at Ramsgate, for instance, and the other languishes at Ventnor, and *vice versâ*; and in treating diseases we have to remember that we treat the individual and not the disease; in other words, the treatment required must depend upon the "temperament," a knowledge of which may enable us to guard against diseases to which we may be particularly liable.

ORIGIN AND SIGNIFICATION OF "TEMPERAMENT."

Temperament is a very old word. It was in use over 2000 years ago and is said to have been originated by Hippocrates 400 B.C. The ancients had no stethoscopes, thermometers, watches, nor instruments for measuring arterial pressure other than the end of the fingers. Moreover, they had no physiological and but [illegible] anatomical knowledge of the internal organs, whi[illegible] neither view as we do nor bring them into [illegible]rdly. In consequence they eagerly cul[illegible] of [illegible]igns, and finding that pe[illegible]ternal conformation [illegible] they attributed th[illegible] the humou[illegible]m, an[illegible] an[illegible]were and phlegmatic temperament. Even in the remote past, dark or fair persons were known to be predisposed to diseases of different types or classes, and the same diseases were known to affect them differently and needed different treatment for their relief. Experienced physicians and surgeons in more modern times, relying on the maxim that we are often better known by our looks than our words, have followed most keenly the study of resemblances and differences in their patients—certainly keenly in this hospital in the time of Dr. Patrick Black, who, without examining them, arranged his out-patients on seats according to the "physiognomy" of their disease. By this experience many of them arrived at a sort of instinct or divination by which the true character and the history of their individual patients could be read in the external features and physical conformation. They were enabled to discover the presence of, and, it is stated, the predisposition to, disease in their patients, to foretell the nature of their illness as well as its probable termination, thus laying the foundation of prognosis, and, as is further added, to proclaim the nature of the moral affections.

The word "temperament"—from *temporare*, to moderate, derived from *tempus*, time, the great temperer—is the most popular and least exact of all the terms used in describing differences of organisation. One writer states that all creeds and opinions are matters of chance and temperament, giving it the widest range and the most varied possible use, but implying that, given a certain personality or certain physical characters, the corresponding mental as well as moral traits may also be predicted. The words *temperamentum*, *temperatura*, *temperatio* have also been used in the same sense, and so have *complexio*, crasis (κρᾶσις); eucrasia, a good temperament; eu-exia (ἕξος), a good constitution; euchymia (χυμός, juice), a good state of the humours. The different mixing or tempering of the constituent parts of the body was assumed to cause the difference between individuals, this difference of organisation being due to a difference in the function or activity of the organs concerned.

To define the word temperament is not an easy task. By some it has been applied to indicate the relation between certain physical states (such as the size and form of the body, the size and shape of the head and face, the colour of the hair, eyes, and complexion) and mental states. Others regard it as the actual combination of certain physical with certain mental characters. There is a danger, however, in reading too much from physical characters to mental traits, and there is no doubt that this has been overdone, minute details and deductions having been inferred which experience would neither warrant nor justify. We ourselves know the impulsiveness, the love of change, and the unwarranted hope of blue-eyed, red-haired people (the sanguine temperament) as contrasted with the caution, persistence, and ambition of the dark-eyed and black-haired (the so-called bilious temperament). Yet surrounding circumstances might so modify natural impulses and tendencies that a carroty-haired girl—a *femme blonde*—might be transformed into the unemotional and simple nature of her black-haired sister, the *femme brune*. John Stuart Mill clearly recognised that differences of bodily structure were correlated with different mental states, and George Eliot went further and declared she never knew brains and red hair associated.

Mainly, however, the term "temperament" came to mean certain physical conditions, and Galen, in a Latin treatise translated by Linacre, suggested nine kinds of temperaments, based upon four simple physical states, which he described as moist, dry, hot, and cold. Four others were obtained by mixing these—viz., hot and moist, hot and dry, cold and moist, cold and dry—the ninth, which he called the balanced temperament, being made up "through the proper mixture" of all the others. According to their preponderating activity and in accordance with the system of humoral pathology the function of the four chief organs in the body gave their names to corresponding temperaments—viz., (1) the heart and blood; (2) the liver and bile; (3) the spleen, which was surmised to secrete black bile; and (4) the brain, with the pituitary body, which secreted phlegm, and thus the varieties described by Galen were reduced to four. In order fancifully to delineate the four temperaments they have been considered analogous to the ages of man and to the seasons of the year—the sanguine corresponded to childhood and spring, the bilio[illegible] to youth and summer, the melancholy to middle age [illegible] autumn, and the phlegmatic to old age and winter.

7159

the progress of experimental physiology the spleen was discovered not to secrete black bile, and on anatomical grounds the atrabilious or melancholy temperament was discarded, and in its place was suggested a nervous one, and we desire to know if such exists?

TEMPERAMENT A TENDENCY TO REACT TO STIMULI.

As to whether temperament is physical or mental, or neither, probably no two authorities are fully agreed, but in our view it is neither a *combination* of states nor their *relation;* neither is it a physical condition but a *mental* "tendency." It will be taken throughout this paper in a psychological sense and as indicating certain reactions or tendencies on the part of the organism, in the first place towards its environment, or in other words, the tendency to certain kinds of conduct, based on the correlation of physical with mental states, and secondly, the reaction of the organism to disease. We cannot fail to recognise that there is a correlation between certain bodily states and certain mental states shown by the appearance of the brain in certain forms of insanity, and there is also a correlation between certain bodily states and certain morbid conditions described as scrofulous, gouty, cancerous, hæmorrhagic, rheumatic, sthenic, and dartrous tendencies; but empirical generalisations such as these must be further investigated before progress can be made in definite and actual correlation. Whilst therefore appreciating the reality of such a thing as "temperament," and whilst accepting it as a psychological tendency, A. Stewart and others who have written on the subject consider the correlations of the four chief types of temperament to be: (1) for the sanguine type, persons who are short and often stout in later life, who have fair complexions, blue eyes, and red hair; mentally active, emotional, and excitable, but lacking in persistence and steadiness and showing a tendency to acute illnesses; (2) for the bilious or choleric, those who are thick set, rather clumsy folk, with dark eyes, hair, and complexions, people who are often gouty or rheumatic, and who are mentally unemotional, deliberate, and jealous; (3) for the phlegmatic or lymphatic, people with bulky forms, light hair, pasty complexions, slow movements, mentally "heavy on hand," slow, and plodding, a type which tends to dementia and diseases of a slow course; and (4) the nervous, with slight, slim, tall figures, large foreheads and pointed chins, dark eyes and sallow skin, those who think quickly, react rapidly, are susceptible, but easily get over their emotions. These tend to suffer from nerve storms, not infrequently ending in insanity. Probably no person has only one or other of these four recognised types, the chief characteristics in any one person partaking of the compounding of all the varieties, hence the necessity for some other more definite classification. Even in twins, whom we should expect to be most alike, there is often a greater divergence than there was between Esau and Jacob.

THE BODY ONLY THE AGENT OF MENTAL EXPRESSION.

If we take the body to be the organ of the mind's expression, and the body must be considered biologically as an aggregate of unit characters each of which has independence of a kind; we shall find that temperament, in the sense of being the aggregate of a man's physical personality, is an untenable theory, and the term has ceased to have any definite anatomical meaning. The human organism, like any other, reacts to its environment, and it is this tendency to react which I shall describe as "temperament." Any stimulus, external or internal, impinging upon any sensory areas of the body tends to come out as movement, and it is this reaction to outward or inward excitement which is the basis of human activity. Precisely as the amœba is seen to contract from the excitement of contiguous particles which act as stimuli to it, so exactly does the human body react to its stimuli. It is this reaction, in my opinion, which is the fundamental quality of temperament, and we know how infinitely varied is this reaction in different individuals. A race or a nation is composed of many individuals, as the individual is composed of many cells, and the national or racial temperament is the tendency it has to react to stimuli from within or from without.

INFLUENCE OF ENVIRONMENT.

The physical organism, as we all know, is the resultant, so to speak, of developmental forces—i.e., it is the result of inheritance. The original gametes—the male and female cell with their chromosomes—unite and become the zygote out of which the individual arises and grows, by the power of certain chemical combinations, through certain states based upon laws, which, although we know little of them, we describe as the laws of inheritance. In the study of heredity we find certain characteristics dominant in the parents repeating themselves in the offspring, which is a blend of all its ancestors, but the influence of the environment must not be overlooked as a controlling power, for "nature" and "nurture" both count. In the course of long ages the surroundings are undoubtedly a great modifying factor upon growth and development, carrying with them also a certain method of reaction which I call a "temperament." The nature of man is "like the dyer's hand, subdued to what it works in." The capability for adaptation and improvement which the history of man records shows so many changes that it would be impossible correctly to infer definite mental qualities from outward appearances. Food, climate, occupation, soil, and the general aspects of Nature all exercise a modifying influence on man's development.

We can tell the East Coast agriculturist, the central manufacturer, and the Western miner from their occupations, food, soil, &c. We can also tell the doctor, lawyer, solicitor, and sailor by the influence of their environment. In the vegetable kingdom we see in plants that the environment counts much as a controlling power. Alpine plants when brought down to the plains assume plain characters, and those characters created by environment become fixed, for the plants come true to the seed, reappearing with their acquired characters when the seed is sown. The same with water plants which as a rule have deeply dissected leaves when growing in water. Land plants thus grown tend to take up the water characters, and these characters reappear again when the seeds of the new plant are sown. The same influence of the environment occurs with plants of the dry desert or with those of moist Equatorial continents. As in plants, so in animals and man. The environment is able to modify appearance, stature, language, customs, and conduct, and, owing to environmental differences, the geographical limitation of man is rarely an ethnographical one, as we know in regard to our own country.

ORIGIN OF THE BRITISH PEOPLE.

Let us briefly review the history of man in the British Islands in order to show his composite origin and his changes by environment, also in order to prove that he cannot possess a simple temperamental type as suggested by some authorities. In the Pleistocene Age, some tens or hundreds of thousands of years back, Great Britain and Ireland were parts of the main land; rivers ran north and west to a coast line far out into the Atlantic, probably where the hundred-fathom soundings show the dip into oceanic depths. In this age lived Palæolithic man as a hunter and fisherman, using flints, bone and horn tools and weapons. As contemporaries he had the mammoth, the cave lions and bears, the straight-tusked elephant, wild horse, hyæna, Irish elk and reindeer, the hippopotamus, and the rhinoceros. He had attained civilisation, as may be seen from the carvings and drawings of the river drifts and the cave remains since collected.

The Glacial epoch came on during this period and swept away the mammoth and its congeners, and with it Palæolithic man. A new era brought a new race from the continent of Europe, and Neolithic man was later succeeded by man of the Bronze Age, then of the Iron Age and of the lake dwellings. Neolithic man, who probably knew nothing of agriculture, was short and dark, dolichocephalic, with a cephalic index of 71 or 72, and with black curly hair. It is stated that curly hair is rarely associated with great intelligence, but this dark type from the Iberian Peninsula is the oldest stock in our country, and its remains are still found in Wales, in some parts of Cornwall, and in the West of Ireland. The Bronze Age saw the arrival of a new blonde race, who were brachycephalic, with a cephalic index of 78, who crossed the Channel about 1200 B.C. and introduced the Aryan tongue into Britain. This fresh immigration came from the parts between the Rhine, the Seine, and the Garonne; the northern became the Goidelic and the more southern, the Belgæ or Galli, became the Brythonic, using a language which became the parent of the present Welsh. Later, we have records of incursions by Phœnician traders and by Greeks from Marseilles, followed by those of

the Danes, Saxons, and Normans. Under such circumstances who can claim for any of the inhabitants of this country a pure temperament such as is academically suggested in the types presented? The absurdity of such a suggestion is too evident. What with the intermixture of races in the past and with local migration in the present (by means of railways and other methods of communication) it is impossible to look upon modern civilised man temperamentally as other than an amalgamation in his own person of different developmental forces, many of them of course arising out of environmental influences. Defoe says:—

"A true-born Englishman's a contradiction,
In speech an irony, in fact a fiction."

RELATIONS OF UNIFORMITY OF STRUCTURE AND QUALITIES OF MIND.

Although the Englishman is made up, as we have shown, of grafts from every race of the Aryan stock, yet abroad he is always "spotted"; at any rate, the hotel keepers seem to find it out! Is the American, the Frenchman, or the German identified by some peculiarity of configuration which is also always associated with certain mental qualities or by certain tendencies in conduct? I venture to deny any such constant association. Uniformity of structure in people is one thing, but the uniform association of structural qualities with qualities of mind or conduct in them is quite another. There is no more reason for considering that certain uniformities of structure (which enable us, for instance, to identify a Jew, a Frenchman, a German, or any other nationality) should imply similar temperaments than there is to suppose that such uniformities of structure or similarity of configuration as enable us to identify members of the same family should imply for each of its members the same temperament or the same mental reaction, a condition we know not to exist. It must not be assumed from racial likeness that structural similarity implies the same invariable association of mental qualities. For this reason we protest against the *physical* explanation of "temperament." The same excitation of the cortical cells in one person, even of the same family and descended from the same ancestors, gives rise to different effects when applied to another member of the family, and it is erroneous to associate physical similarity with uniform mental qualities.

CONSTANCY OF SOME FAMILY PECULIARITIES.

It is true that there are family peculiarities which are very constant—such, for example, is the nose of the Bourbon Royal houses of France, Spain, and Naples, or the Hapsburg lip,—yet these outward marks imply no uniform mental correlation. Analogous peculiarities may characterise races, yet they may not imply similar mental tendencies or temperaments in these races. Some of these family peculiarities are often in the nature of degenerate stigmata. The Hapsburg lip is not inherited by the females, yet it is transmitted by them. Napoleon I. married an Archduchess of Austria, and her son, the King of Rome, inherited the Hapsburg characters. Charles V., the greatest European potentate of the sixteenth century, had such a well-marked lower lip that each time he ate, it is said to have touched his nose. Philip II., son of Charles V., possessed this prognathous skull and lip of the Hapsburgs, and he was an unmistakable descendant; but Don John of Austria, although acknowledged to be another son, had none of these characters, and history has since rejected this filiation and has relegated his ancestry to the German servant, Barbe Blomberg, and her vulgar paramour. Some doubt has existed as to the legitimate claims of Louis XVII., as he inherited none of the prognathism of Louis XVI. and Marie Antoinette, who were both Hapsburgs.

THE FACE AS AN INDEX TO CHARACTER.

I do not say that much information as to mental character is not to be obtained from the face. The whole trend of experience is the other way; all I say is that too much trust must not be laid upon the face, for we are apt to deceive ourselves and be deceived by excessive reliance upon the physiognomy. Many attempts have been made to read temperamental traits from the face, and faces have been divided into the square for the bilious and lymphatic, tapering for the sanguine, and for the reflective and introspective the so-called melancholy face; but it hardly need be said this question of expression implies a much more complicated inference than seems to us on the surface, for we have the square-jawed midnight marauder—the typical "Bill Sykes," and we have the tapering face of this man's tool—viz., the sneak-thief, who is content with minor achievements, such as stealing purses and picking ladies' pockets in the intervals of loafing. There is no doubt the physiognomy has been greatly exploited as a field for information in regard to character. As an expression of the emotions it is certainly of value, particularly of those fundamental emotions relating to pleasure and pain, for the face, like the barometer, is a good indicator of *existing* emotional weather, but too much confidence must not be placed in the face as the chief interpretative medium of character. In regard to the elements of the physiognomy, the eyes are looked upon as the "pole-star" for those who seek guidance as to the emotions: the eyes of Chatterton had "fire rolling at the bottom of them," and those of Burns were "like coals of living fire," and Sir Walter Scott's "literally glowed"; but the hand is also a valuable guide. Nevertheless, I am inclined to think that the most reliable element in the face is the mouth. Possibly the more fleeting and transient feelings of the moment are better reflected in the eye; whereas the fixed, firm, decisive, and permanent constituents of character are in the mouth. We all know the roving eye which looks upon everything and sees nothing, and we recognise the inconstancy conveyed by the shifting eye.

As to the general mental disposition, we rightly associate the different emotions—e.g., joy, caprice, anger, fear, and ambition—not with the bony framework of the face, but with the more mobile features controlled by the muscles and nerves of the face. It is the *tout ensemble*, the whole assemblage of the visage in which we see emotion and which rightly show character. For instance, we know one person to be suffering from melancholia, another from mania, a third from dementia, a fourth from confirmed epilepsy, and a fifth from general paralysis by outward facial characteristics. A sixth, perhaps a summary of all the others, which forms the basis of the insane temperament, gives, on the other hand, no indication by physical signs—i.e., one needs to find out the mental reaction to ascertain the temperament. Neither the highest powers of the microscope nor the most skilled chemist would be able to say that a person possessed the temperament of the paranoiac, who is the most dangerous as well as the most chronic of all the varieties of insanity. For this it is necessary to ascertain the mental reaction.

CLASSIFICATION BASED ON THE MENTAL REACTION.

The mental reaction or tendency to act must be taken as the only guide to the temperament or the personality, and mental reaction originates primarily out of the master structure—viz., the brain, which gives to the individual the form of character or the conduct he tends to. The brain of man differs from that of the lower animals, and there is also a racial difference, for the brain of an Englishman differs from that of a Chinaman. There is a diversity in shape, weight, size, quality, and convolutional pattern, and a corresponding diversity is seen in their mental reaction. It is the reaction of this master tissue that forms the basis of temperament. In other words, it is the reaction to the environment which constitutes the scheme for its proper classification or subdivision, and this is the one which has been verified by observations and which, to quote Ribot, may be divided into four chief types—viz., firstly, the active or responsive; secondly, the sensitive or receptive; thirdly, the apathetic, indifferent or amorphous; and lastly, the unstable or the nervous. These portray fundamental types of character, and they are based upon physiological observation. Man, as we know, feels and acts and wills according to the increasing definiteness or distinctness of some motive depending upon the inhibiting power of the person himself, and so, by adopting this scheme, we have a classification of temperaments on a physiological as well as a psychological basis.

THE ACTIVE OR RESPONSIVE TYPE.

Let us take, firstly, the active or the responsive type. We are all familiar with the strong tendency to action of some of our acquaintances or friends, as well as of some characters in history or fiction whose lives seem to be always directed outwards. The heroes of historical novels (as pointed out by Margaret Ashmun) and all knights of the sword and pistol are of this type. These persons are people of purposeful vigour, full of courage, and they love action,

excitement, and adventure. They are the roystering dare-devils of heroic novels, brimming over with superabundant spirits and full of the zest of life, all action, and "damn the consequences." They are always optimistic, and they exhibit in their persons human possibility to the Nth Power. They are the giants and gods of mythology. Oliver Cromwell and Wellington remind us of the active type, and in Shakespeare Prince Hal and Hotspur are also of this type. D'Artagnan in Dumas' "Three Musketeers" is another example, and the personification of the type is shown in the classical descriptions of Hector, Achilles, Odyssey, Æneas, and possibly Joan of Arc, but it is not the fashion for women to be of the active resolute character, although about 1 in every 18 women is thus distinguished. As they are unable to pull down Hyde Park railings when they have revolted against deep-felt grievances they are laughed at and jeered when they attempt to leave the polite emotions for an active campaign. In further derogation of the gentler sex it is suggested that owing to the rarity of intellectual ability in women they have often played larger parts in the world's history than would be credited to men possessing similar achievements—that is to say, equal ability in man would not permit him to play a similarly large part. Mrs. Elizabeth Montagu, who obtained fame as a leader of society and an authoress, who attacked Voltaire; Mrs. Mary Somerville, who was acknowledged as a scientific writer on the spectrum and on Laplace, and possibly Miss Hannah More, the intimate of Garrick and the authoress of religious tracts, were women of this class. In domestic life the Mistress Page of the *Merry Wives of Windsor* is a cheerful, sprightly, active, and quick-witted woman, who deserves her husband's confidence and has it by her faithful, true-hearted allegiance to him; she is not to be taken in by the "greasy knight" Falstaff. Mistress Ford is another delightfully happy character, the active sunshine of the home, transparent and cheerful. Richard III. may be taken as a practical, direct, and promptly active man, the most wonderfully energetic and skilful murderer that ever sat upon a throne. A crooked and ambitious king, full of energy and insincere, he was a good example of the restless, active type.

THE SENSITIVE TYPE.

The sensitive kind, which is our ideal of refined womanhood, is the next type. The emotional type that sympathises with distress, that is quick to perceive and ready to respond, forms the list of attractive heroines of most of our love stories, and Shakespeare has them in abundance. Portia, the lady of Belmont, is the contemplative variety of this type, and she has been described by C. Cowden Clarke as a lovely specimen of a lovely woman. Like all distinguished characters, she has been roundly abused. She has been accused of pedantry and affectation, of conceit of learning, and of being the antipodes of modesty, but she showed courage at the right moment; she had ready wit and great presence of mind, and she is probably the most cheerful and pleasant spirited of Shakespeare's characters. Juliet is another of Shakespeare's love heroines, emotional and sensitive. From the moment she learns of Romeo's banishment, through her agonised pleadings with her parents to the subsequent interview with Friar Lawrence, as well as in the scene where she drinks the sleeping draught, we see her ceasing to be the weak loving girl of sixteen, pouring out the beauty of girlhood, and suddenly becoming a strong self-reliant woman in whom all the most powerful emotions and ardour of the really sensitive lover are fully portrayed. The delicate poetical love of Viola is the sweetest and tenderest emotion that ever informed a human heart. Jane Eyre and Lucy Snow are other characters which represent the sensitive temperament. Nor is this type limited exclusively to women; there are men of this type, and Mark Antony, if I interpret him rightly, was of this temperament. He was sensitive, and, although a warrior, he was effeminate and fond of pleasures. He married Fulvia, whom he repudiated for Octavia, and she was cast away for Cleopatra. Marcus Junius Brutus and probably Hamlet were also of the contemplative sensitive type. Job, Christian in the "Pilgrim's Progress," and Robert Elsmere may also be placed in the same category.

THE APATHETIC TYPE.

The other division is the mentally apathetic, the characterless or amorphous group, not because there is no character in these, but because most of the active and the sensitive elements of reaction are balanced and there is a suppression of any one definite element. These people do not feel deeply nor strongly, they are often heedless of others and are egotistical. Falstaff was of this type. He was charged with a host of vices; he was coward, swindler, liar, cheat, and braggart. He had a laughable effrontery, but he was no hypocrite. He was irrepressibly human and was always the friend of Prince Hal. There is much that is selfish and cold in many of this class, and they are not as a rule of the sensitive or the emotional set. Shylock the Jew, with his morality founded on disbelief in magnanimity and goodness, is of this order, and possibly so was Beatrice in *Much Ado About Nothing*. Her marriage with Benedick was a *fin de siècle* union not founded upon love but upon what might be called "friendly concoction." Cardinal Wolsey, although active and unscrupulous, was of the cold, calculating, and impervious manner, which, however, found its mastery in that of his king. Possibly Richelieu and Iago were also of this group.

I do not say these are the only types, as each of them is found mixed with the other, and even the resulting compound does not cover the whole ground of temperaments. Let us therefore see whether or not there is yet another kind, and which for the want of a better term we may describe as the purely "nervous."

THE UNSTABLE OR NERVOUS.

Into what class are we to place such characters as are pourtrayed by the Reubens, "Unstable as water, thou shalt not excel"? What about the many clever people who are often so scintillatingly brilliant that they can be best described as geniuses, but who are, nevertheless, so uncertain in their mental reaction that we are bound to call them capricious, fickle, explosive, and unreliable; persons whose friends are unable to predict what they will do next, who cannot be depended upon for kindness, devotion, or love even to their own relations and dependents, whose own natures know no standard of consideration, and who are described as wanting or lacking in mental poise. That such persons exist is without doubt, and some may be known among our own acquaintances. Take the well-known family trees which demonstrate insanity, epilepsy, suicidal tendencies, anti-social conditions, and bodily abnormalities, such as night-blindness, Huntington's chorea, muscular dystrophies, hæmophilia, or diabetes.

How are we to classify these people who suffer from such nervous diseases as are unknown among barbarous or even among half-civilised people—those, for instance, who are hysterical or eccentric, who are peculiar, or "cranky"; those who suffer from somnambulism or sleeplessness, from unreasonable irritability, from obsessions or nervous exhaustion, who may even be epileptic, yet are often extremely capable and often very talented and distinguished, but who nevertheless are abnormally susceptible to impressions, who suffer from functional neuroses of various kinds, who have neuralgias and headaches, who are dyspeptic owing to delicate digestions or premature decay of the teeth, who suffer from neurasthenias, and who are unduly sensitive to alcoholic stimulants, and who may even be moral degenerates, although possessing marked mental superiority in many directions? That such conditions exist compatible with high intellectual ability is seen from the history of many of our great men. Nature rarely begets a genius, but she does not often create imbeciles or idiots, she dislikes extremes of all kinds, and her tendency is towards the average or normal type both in mental and physical conformation.

GENIUS AND NERVOUS INSTABILITY.

Many persons described as possessing genius in certain specified lines are, as J. Nisbet has shown, of this class. They are often predisposed to states of extreme irritability, and they suffer from intense emotional disturbances resulting in severe nerve storms or outbursts of motor violence which can only be described as that of subacute mania. The rapidity of their mental processes and the intensity of their conative tendencies when aroused know no control and such are often out of all proportion to the amount of the stimulus.

Into what class other than the nervous or the neurotic are we to enter such persons? In this analysis we are bound to give much consideration to the maxim that "like begets like," yet in several instances there has possibly been a

segregation of some unit characters, although admittedly not on Mendelian lines. Shakespeare, the greatest poetic genius the world has ever seen, stands alone. He appears to have had no family history of ability, and little is personally known of him, which shows that mental characters, although distinguishable, are often unanalysable. The genealogy of the poet Cowper will illustrate my point. There was mental unsoundness on both sides of his ancestors, who were also distinguished for fame, as he was the grandson of a Justice and the great nephew of a Lord Chancellor. He suffered from religious hallucinations and had the strongest suicidal tendency, having to be cared for in an asylum for a period of over a year, yet he wrote "John Gilpin" when suffering from intense melancholia.

The poet Shelley had an insane ancestry; his grandfather suffered from melancholia and was a miser, but wealthy. His father showed similar tendencies. His mother was violent and domineering, but of lonely and solitary habits. At Eton he was called "mad Shelley," and the day before he was drowned at Spezzia, at the age of 30, he saw vivid hallucinations. In his picture his eyes are large and animated and wild, his voice was said to be high, weak, and discordant, and he was described as shy, solitary, anti-social, and the subject of ecstatic visions. Charles and Mary Lamb had a convergent heredity of nervous instability and nervous disease. Their mother died from dementia and paralysis at 50, and Charles died at 60 from what he himself described as the "cursed drinking." He was only 5 ft. in height, he stammered, and always suffered from headaches. At the age of 20 he had to be placed in an asylum, whilst his sister Mary stabbed her mother to the heart and killed her whilst insane. Wordsworth, who was a poet laureate, and his sister Dorothy are almost a parallel to Charles and Mary Lamb. Dorothy, like Mary, was insane and, like Mary, she was poetical and in the closest sympathy with her brother's pursuits. Dorothy Wordsworth was described by De Quincey as having eyes wild and staring, with an embarrassed and distressing utterance, a creature of fiery impulse. She later became mentally afflicted and never recovered her reason. Wordsworth himself described his sister as a "confirmed invalid." One of Wordsworth's children died from paralysis, another daughter was peculiar, being alternately gentle and vehement, and suffering from a form of insanity described to-day as of the "manic-depressive" variety. Wordsworth's father died at 42, and, like the fathers of many insane persons, was described as a man of great force of character, and his mother died from phthisis at 31.

The Coleridge family had a strongly marked insane history. The father of Samuel Taylor Coleridge was eccentric and absent-minded, and his mother is stated to have been uneducated and simple. He himself ran away from college, he quarrelled with his brother as a boy, and left home, being absent all night without apparent reason. Later in life he left his wife and children and went off to Malta. At the age of 30 he was broken down, and he died a wreck at 62. His son Hartley drank himself to death and died demented at 52. Southey came of an insane stock on his mother's side, who herself had paralysis in infancy. He had a maternal uncle described as "idiotic." His paternal uncle left his estate to a footman rather than to his sister who lived with him and who was dependent upon him. Carlyle described him as the "excitablest man" he ever met, and he died from dementia. His wife became insane, and also some of their children. He was described as having the most vehement pair of hazel eyes. The Sheridan family is notorious for neuropathic and psychopathic ancestry. The mother of Richard Brinsley Sheridan, the dramatist, was paralysed, and died demented at 42. His maternal grandfather also sank into dementia, and a maternal uncle was described as "absent-minded." He married twice, marrying the second wife a few weeks after the death of his first, and winning her, it is said, with copies of the love letters sent to his first wife. He died in debt and *déclassé* through drink. Only one son left issue, and he married into a healthy stock, of which famous issue has resulted.

Sir Walter Scott's family was permeated with nerve disorder. His father died from organic dementia, and his mother was aphasic and died from post-hemiplegic dementia. The maternal uncle also became demented. He himself had two sons who died childless, and two daughters, one of whom died from brain fever and the other, Mrs. Lockhart, from phthisis. His ambition to found a family "sleeps with him." Burns's father had an "ungovernable irascibility" and he himself was the victim of drunkenness and died at 37. One thing he loved since the age of 15, and that was "woman." He used to say his frame was blasted with a deep incurable melancholia which poisoned his existence.

Pope was deformed, rickety, and susceptible. A picture of him proposing to Lady Mary Wortley Montagu is in the National Gallery. Keats is described as neuropathic to the tips of his fingers. He had an ungovernable temper and was dwarfish, being only 5 ft. high. He had a passionate admiration for "Fanny Brawne," and Shelley said his alternation of despondent gloom and emotional passion was exactly like insanity. He had no trace of eminence in his ancestry, and his temperament and genius are probably a good illustration of a spontaneous variation. Byron's mother was most unbalanced, and his maternal grandfather suffered from melancholia and committed suicide. Another relative committed suicide with poison. Byron succeeded his grand-uncle, the "mad and wicked" Lord Byron. His father, the "mad Jack Byron," died from suicide whilst insane. Byron's father ran away with the Marchioness of Carmarthen, an heiress, whom he married and killed by cruelty, and treated his second wife, Miss Gordon, the same. A converging heredity of this kind in the ancestors fills our asylums. Byron was correctly described by his most intimate friends as "too mad, bad, and dangerous to know." His daughter Ada married Lord Lovelace, and her son, the Viscount Ockham, served as a common seaman and worked at Millwall as a ship's carpenter. Byron was tortured by hallucinations, he drank, and died an epileptic at 36.

Milton was gouty and lost his sight from inherited blindness. He was said to be most tyrannical in his home life, and is stated to have led his daughters a miserable time, accusing them of selling their father's works and cheating. He had four children, a son who is said to have died in infancy from ill usage, one daughter who was blind, another a cripple, and a third one died later. His own brother was described as a "disreputable judge," and in the collaterals were many "ne'er-do-wells." I quote this instance, as insanity is only one of a group of neuroses, and genius has to be paid for at the cost of many penalties.

Let us now trace the inheritance and the mental reaction in the biographies of some of the most eminent musicians, and we shall see the same penalty for genius and the same ravages of psychosis and neurosis, using these terms in their pathological sense. The genealogy of the Bach family has been traced for 200 years, from the founder, who was a baker, to Sebastian Bach, the climax of musical talent. Bach had 20 children, but no issue remains to perpetuate the distinctions of the father. Although many of the Bachs married musical people the family record is one of sickness, blindness, drunkenness, and mental defect. Although we can breed Arab horses, Derby winners, and prize cattle, it has hitherto not been possible to produce a "musical breed," showing the unfitness of genius to survive in a world requiring many adaptations, and the incapability of genius to continue its own distinctions. Schumann suffered from recurrent melancholia with suicidal impulses. His mother was singular and eccentric, and a sister died from what we now describe as "dementia præcox." Wagner was a wild and erratic boy, filled with the wildest mysticism. He grew up with a violent temperament and his actions were often uncontrollable. He had a mania for silks and satins, with which he always dressed himself to compose music. When travelling he also carried these to decorate his rooms, and when he died he requested that his room should be upholstered in pink and pale-blue satin. Schubert was worn out and died at 31. Beethoven suffered from a form of paranoia described as mania migratoria; he was always changing his rooms and was paying for three or four different lodgings at the same time. He seems to have alienated his best friends through suspicious jealousy and false accusations. He began to get deaf about the age of 30, and in later life was completely deaf, so that much of the music he composed he himself never heard.

CONCLUDING REMARKS.

From what has been said it will be readily seen that genius may often prove to be a golden idol with feet of clay. Man is firstly a vertebrate mammal with the instincts of the

animal, but he has the power of inhibition and of auto-criticism, and through the influence of his environment he has attained a veneer of civilisation, and it is interesting to note that in insanity these acquisitions of his progress are gradually dissociated and shed in the inverse order of their acquirement, until at last man is left a wreck barely above the level of the animal. The cause of this reduction in insanity is probably some physical process in the cortical cells, or, in other words, some chemical change has occurred in the neurones, either directly through the influence of some poison generated from within or introduced from without the body, or indirectly by means of the environment, favoured, of course, by some inherited predisposition; and it is the study of man biologically—that is to say, the observation of his general activity or his total reaction under the influence of physical and psychological impressions—that enables us to infer the kind of temperament a man possesses. As we have seen, the predisposition to states of instability of control may be associated with distinguished mental superiority, and it is the degree of sensitiveness to pleasure and pain, the degree of motor restlessness and the degree of emotional tone exhibited by the individual which justify us in concluding that there is or is not present a temperament which we are entitled to describe as the neurotic, and it is by foreseeing this temperament that we can promote happiness and harmony where otherwise there would be intolerance, strife, and discordance. The more we see of the deviations of mental reaction and of physical structures the more we must be convinced that special modes of nutrition must have their special physiological expression, and that our work of prevention and relief as medical men is as important for the welfare of the community and the progress of the race as it must be for the well-being of the individual.

AN ABSTRACT OF

The Samuel Hyde Memorial Lectures

ON

OUTLINES OF MEDICAL HYDROLOGY.

Delivered before the Balneological and Climatological Section of the Royal Society of Medicine on May 15th, 17th, and 19th, 1911.

BY R. FORTESCUE FOX, M.D. LOND., F.R.MET.S.

LECTURE I.

Delivered on May 15th.

ANALYSIS AND DEFINITIONS.

THE association of the medical science of climates with that of baths and waters is not accidental, nor founded only upon a convenient grouping of two chief modes of physical therapeutics. It is a real and essential connexion, for whilst the influence of climates often operates alone it is inseparable from the action of baths. In truth, the climatic factor enters into every balneological equation. At every spa the influence of the waters and baths and of the local climate are inextricably mingled. Whenever a patient is submitted to baths or waters the climatic factor is an accessory, and sometimes a dominant, influence. For this reason the study of medical climatology, both in its general principles and in its local and special applications, can never be overlooked by the spa physician.

CLIMATE IN RELATION TO SPAS.

The various spas, both British and foreign, enjoy a great variety of climates, and it would be possible, and indeed desirable, that they should be grouped according to their climatic characters. Many waters and baths, apart from the climate, produce, with minor individual differences, the same general effects. The climate is often, therefore, the determining factor in the choice of a particular spa for invalids—and in this matter the general condition and temperament of the individual must be considered as much as his malady. Moreover, an appropriate climate will reinforce the effect of the spa treatment, as an unsuitable one will antagonise it. This applies with especial force to cardio-vascular and nervous disorders. A large number of patients so affected are benefited more than by any other form of treatment by subthermal baths, still or gaseous. Of these cases, some should never be sent away from home for treatment; others do best in the cool and bracing climates of our own island; some require in association with bath treatment the cooler temperatures of northern latitudes or sub-Alpine stations; and for only a certain number is the summer climate of warm valleys appropriate. The question of altitude should be particularly considered in its influence on the action of baths. Among the thermal baths of Europe there is a wide available range, from 100 to 5000 ft. It may be noted here that for the treatment of circulatory disorders Buxton, Harrogate, and Llandrindod all have a suitable medium elevation, and that Strathpeffer, although nearer to sea-level, has the compensating advantage of a more northern latitude.

Hot or thermal baths are best borne in cool places. Indeed, in the case of delicate persons they can only be taken with safety in a cool climate. Otherwise, the enervating effect of heat, added to that of the baths, may bring on a serious condition of what may be called "thermal debility," which is sometimes prolonged for many months, and may even be fatal. Thermal debility, which is the effect of an excessive or too prolonged thermal influence, is a too common and undesirable result of a course of baths. Among the many examples that have come to my knowledge I have sometimes thought that the fault lay quite as much in a bad choice of climate as with the baths themselves. I need not apologise for this incidental reference to what is in truth the most serious danger of spa treatment. We know that heat is one of those powerful stimulants that very rapidly become depressant. Its first effect upon the skin is vascular dilatation and increase of sweat, resulting in compensatory loss of heat. This pronounced and obvious action cannot escape notice, but the reaction of heat comes more slowly than that of cold, and sometimes in a gradual and insidious manner, and it may be after the treatment has ceased. The lessened heat production from thermal applications, the lowering of blood pressure, and the elevation of the temperature of the blood from prolonged and repeated hot baths, all diminish nervous and muscular energy, and bring about exhaustion of the spinal and cerebral centres and the heart. It follows that the reaction to heat must in practice be avoided with as much care as the reaction to cold is encouraged and promoted. In many conditions of senile weakness and premature degenerative changes the indication is for a mildly tonic and sedative climate. The only appropriate remedy, whether of bath or climate, must be temperate, soothing, sedative.

FACTORS IN HYDROLOGICAL TREATMENT.

The medical use of springs and of baths comprehends a bewildering variety both in the potable water and in the methods of its application. Hitherto, this too obvious diversity has rather obscured the truth that all such treatments have certain essential characteristics in common. The action of pure, sweet, and fresh water is the first of these common factors. The quality of *freshness* is of the first importance in the administration of waters, and springs differ widely in respect to this quality. It is not necessary to accept without reserve the theory of Armand Gautier that the water of certain thermal springs is in a real sense chemically "new," having the heightened activity of nascent matter. But it is common knowledge that the flowing, or in the old parlance the "living," fresh water of the fountain has a different property from that of the same water when still, contained in reservoirs or bottled. Consequently certain waters produce their most powerful effect when employed either for drinking or externally at the source.

The second common factor in these methods of treatment is not less important—namely, *heat*. For warm-blooded animals living in a cooler medium, heat is measured relatively to the temperature of the body. *Plus* or *minus* applications of heat are naturally inseparable from waters, whether internally or externally used. Baths act in the main as vehicles of energy, of which heat is the chief form. Water is in respect to the human body the commonest and most convenient medium of energy, but it is convenient to include in the category of bath treatment other media, such as dry sand and air, by which heat can be abstracted or conveyed. Again, inasmuch as baths of different kinds embrace the

chief forms of heat treatment or thermotherapy, it is convenient to include with baths the other forms of thermotherapy such as insolation, thermo-penetration, and artificial radiant heat, for which no physical medium is needed. It follows that in this division of our subject ought to be placed all our knowledge with reference to the effects of temperature (*plus* and *minus*) upon the functions of the body in health and disease, notably the effects upon heat production and conservation, and upon the processes of tissue change, and especially on the dissociation of tissues. All these actions are excited through the skin. This, again, will lead to a deeper study of the functions of the skin as the most extensive and sensitive organ of the body. I have long believed that when the relations of cutaneous conditions, and especially subnormal cutaneous temperature, to chronic disease have been more accurately ascertained, the use of thermotherapy by means of baths will be widely extended. Take, for example, hot pediluvia, which are so much employed at the baths of Mont Dore and elsewhere in France in order to produce an effect that was long ago described as "derivative" or "revulsive." In this country there are many persons in whom the cutaneous circulation is permanently defective, and the surface temperature, more particularly of the feet, sinks to 10° or 15° below normal. Systematic foot-baths at a temperature of 110° to 120° F. provide a means of restoring the peripheral circulation and relieving high arterial tension in many cases. It is clear that the thermal effects of baths, whether general or local, are deserving of attentive study.

We have next to notice the factors that depend upon the particular qualities of medicinal waters. Each spring has its own proper ingredients, and these must have their pharmacological effects, beneficial or otherwise. Under this designation we find certain gases, salts, acids, metallic elements, ferments, and other organic matters, all of which belong to medicinal springs, and the study of which must therefore be germane to the science of waters. We have also to take account of the particular *physical properties* of waters. Their temperature, electrical condition, tonicity, and radio-activity fall under this heading. Important researches during recent years have thrown much light upon the physico-chemical properties of medicinal waters, particularly of the thermal springs, and still much remains to be learned.

Thus we may conclude that the medical doctrine of water embraces two great branches. The first concerns itself with the use of this element in medicine solely as a vehicle of energy, whilst the other branch has to do with the various ingredients and physical properties of medicinal springs, and of the emanations and deposits in connexion with springs, and with their chemical and physical action upon the body, whether taken internally or applied either locally or generally to its surface.

QUESTION OF NOMENCLATURE.

What single comprehensive name can be applied to the whole science? It is surely unnecessary to argue the convenience, nay, the necessity, for such a general term. To meet the exigencies of the case such a name must satisfy certain necessary requirements. It should be inclusive of all the medical uses of water; it should be distinctive, and it should also, as far as possible, conform to, or be capable of, international use. It has seemed to me that the time may be ripe for reconsidering in this country the nomenclature of this branch of medical science. The subject-matter has, indeed, undergone so rapid development, even in our time, that the terminology of the last century has become inaccurate and even misleading. The varying connotations given to familiar words cause an unnecessary confusion, and the fundamental unity of the whole subject may be overlooked for want of a simple and inclusive name.

THE TERMS "BALNEOLOGY" AND "HYDROTHERAPY."

The word "balneology" appears to be a new one, and was but seldom used before the middle of last century. My earliest example is in 1840, when Krahmer of Leipsic published a review of the "balneological" literature of the preceding year. About 1870 the words "balneology" and "balneological" found their way into this country, and until the present time have been generally employed in England and in Northern and Central Europe. So far as I am aware, in spite of their wider dictionary meaning, their connotation is strictly limited by all authors to the properties and uses of *medicinal* springs. The various actions of water and heat are excluded. Although, as we have already seen, these form essential factors of all treatment by means of water and baths, they have been made to form a separate study under the name of hydrotherapeutics. In France, Italy, and Spain the term "balneology" has not found acceptance, although the expression "balneotherapy" is sometimes used as descriptive of a treatment.

It is true that derivation is a poor guide to the meaning and use of words, even in science; but the purist might urge that balneology (from *balneum*, a bath) should rightly have to do only with the *external* use of water. Custom has, on the one hand, *restricted* its application to the use of medicinal waters, and, on the other, *widened* it to their employment internally as well as in the form of baths. A more serious objection to the claim of balneology to be a proper name for the whole science of waters is that it is too narrow, and that modern usage has confined its connotations to the medicinal spring.

According to the Oxford Dictionary, hydrotherapeutics is defined as "that part of medical science which treats of the therapeutic application of water." In the works which I have quoted there has been, so far as I am aware, no question of applying this term to medicinal waters. I must now refer to a tendency in some of the most recent writers[1] on hydrotherapy to enlarge the connotation of that word. It is even proposed to include under hydrotherapy the whole science of waters and of baths. I think it is not difficult to trace the origin of this proposal. For more than a generation the accurate study and practice of hydrotherapy had proved the efficacy of simple thermal applications in many disorders. As the part played by these great primary and general properties of all waters became evident, so the secondary and particular qualities of the springs naturally waned in estimation. The great reliance that was formerly placed upon the cutaneous absorption of the ingredients of mineral baths was shown in many cases to be unfounded by the discovery that comparatively little absorption of saline matter takes place through the uninjured skin. And the fact that widely different medicinal springs have been supposed to exercise the same effect, and are constantly resorted to for the same ailments, was held to show not only the importance of those qualities which waters have in common, but the insignificance of those in which they differ. The proposed nomenclature is therefore not so much an extension of the range of hydrotherapy as a denial of the supposed active qualities of the medicinal spring. I submit, with all deference, that it is founded upon an imperfect and hasty generalisation. Moreover, I would venture to say that hydrotherapy is not the name of a science. It signifies quite correctly an art or treatment. For more than half a century the word has been consistently applied in the medical literature of several languages to the use of sweet water. It would therefore violate an established and convenient usage, and introduce confusion, if it was now sought to employ it so as to include the particular and distinctive properties of the medicinal spring. In a recent letter Dr. Frankenhausen, lecturer in "balneology" at the University of Berlin, writes me: "In Germany, hydrotherapy and balneology are sharply divided departments of medicine. By hydrotherapy we understand the application of hot and cold water. With this is connected thermotherapy, steam, hot air, and incandescent-light baths. By balneotherapy we understand the therapy of mineral waters, in which, as a rule, different temperatures are of small account, but the chemical characters of the waters, climate, diet, &c., are of importance."

MEDICAL HYDROLOGY AND ITS DEFINITION.

By a process of exclusion we are led to the belief that the proper name for the whole science of water and of waters in medicine is *medical hydrology*. For many years the name has been widely employed on the continent of Europe. A literature of medical hydrology, including the whole subject of hydrotherapy and of medicinal springs, has grown up, particularly among the Latin races, and periodical meetings of congresses under this name in different countries have done much to promote and coördinate its study.

It would seem that philology offers no bar to our use of the word in a medical sense. And I venture to submit that the expression *medical hydrology* satisfies the three essential

[1] See Guy Hinsdale in Hydrotherapy, Philadelphia and London, 1910.

conditions with which we set out. That it is distinctive cannot be denied; that it is sufficiently comprehensive is also evident; and it is also, as far as may be, in conformity with international usage. We may, accordingly, define the name as follows: "Medical hydrology is the science of waters, vapours and mineral, or organic deposits in connexion with waters, as used in medicine, both by internal administration, and in the form of baths and applications."

A SHORT CHEMICAL STUDY OF A CASE OF CYCLIC VOMITING, WITH SOME REMARKS ON CREATINURIA AND ACIDOSIS.

BY EDWARD MELLANBY, M.A., M.B. CANTAB.,
BEIT MEMORIAL RESEARCH FELLOW.
(*From the Physiological Laboratory of St. Thomas's Hospital.*)

THE patient was a boy aged 6 years. He was admitted to St. Thomas's Hospital on May 21st, 1910, under the care of Dr. C. R. Box, who was responsible for the clinical conduct of the case and with whose concurrence the investigation was carried out. The patient was discharged on July 18th. According to his mother, he had been liable to attacks of vomiting and great prostration almost every month since his birth. The attacks lasted four or five days and were accompanied by feverishness and constipation. He was not subject to constipation except at these periods.

On admission to hospital the child was restless and fidgety. The movements, however, were not choreiform. He was very pale. The abdomen was poorly covered but moved well on respiration, and no abnormal masses or peristalsis were observed. The liver dulness extended from the sixth rib in the nipple line to the costal margin and the spleen was not palpable. The thoracic viscera showed no abnormality. The knee-jerks were normal and the plantar reflex flexor. The temperature was 98° F., the pulse was 116, and the respirations were 24 per minute. The urine was of specific gravity 1035, acid; it contained no albumin and no sugar; acetone was present; no blood, no pus.

Course of illness.—During the patient's stay of two months in the hospital he had two attacks of illness, the first one lasting from June 1st to 6th, the second from July 2nd to 6th. During the attacks, although vomiting was present, yet it was not a prominent feature. Naturally a nervous child, at the approach of each attack this condition was exaggerated, and he would sit up in bed and nervously move his hands. When the attack was at a climax the patient lay curled up in bed and refused all food. Although between the attacks his temperature remained normal, yet during the attack the temperature varied greatly between normal and 104·5°. At this time the urine was very scanty and measured on one day only 1 oz. It contained much acetone and diacetic acid. He gradually returned to a normal condition on the fourth day from the onset, the temperature oscillations diminishing, and the volume of urine gradually increasing. Gradually, also, the ability to take food returned.

A very prominent point was the extremely rapid loss of weight that occurred during the attacks. For instance, from May 28th to June 4th the child's weight diminished from 2 st. 3 lb. 15 oz. to 2 st. 2 lb. 6 oz.—i.e., 1 lb. 9 oz. Also from July 1st to July 6th the loss was from 2 st. 7 lb. 2 oz. to 2 st. 4 lb. 15 oz.—i.e., 2 lb. 3 oz.

Current Views on Cyclic Vomiting in Children.

From a review of the literature dealing with this subject it is apparent that the cause or causes are very obscure. The physician in his search for a cause has always had one standby in such cases, and that is the presence of an acidosis, involving the excretion in the urine of large quantities of β oxybutyric acid, aceto-acetic acid, and acetone. It is therefore fashionable, since it is also generally accepted that the symptoms of diabetic coma are the results of acidosis, to ascribe attacks of cyclic vomiting to the accumulation in the tissues of large quantities of β oxybutyric acid and aceto-acetic acid. Langmead [1] thinks that the intestinal tract forms some poison which, being absorbed into the portal circulation, acts directly on the liver and so causes a fatty infiltration of that organ with subsequent acid poisoning.

The central point about which Howland and Richards [2] concentrate is the unstable nervous system of a patient liable to this complaint. They regard shock or excitement as sufficient to disturb the whole metabolism, causing diminished power of oxidation and the circulation of the poisonous, unoxidised substances in the blood. The body tries to get rid of them by excretion into the stomach, and intestine, so that vomiting is the eliminating and protective mechanism called into vogue by the body in this condition. They also comment upon the excretion of indol compounds at this period, and show that indol emphasises the poisoning effect of small doses of potassium cyanide.

Ewing [3] regards the condition as depending upon a disturbance of metabolism due to defective function of the liver, with which is related the defective fat combustion, and associated also with poisoning by intestinal putrefactive products.

Comby [4] has alleged a much more definite cause when he ascribes the condition to chronic appendicitis. He describes the cure of eight patients where appendicectomy was performed, while three patients remained uncured by the operation.

A case recently described by Dr. A. E. Russell [5] seems to point to another possible cause in some cases of cyclic vomiting at least. In his patient the post-mortem examination revealed a markedly thickened pylorus, and he ascribes the vomiting to a hypertrophically stenosed orifice. The starvation which must of necessity accompany such a condition would be sufficient to account for the acidosis, while the death of the child he considers as due to inanition and exhaustion. Post-mortem examinations in other cases do not make it evident that a stenosed pylorus is a common cause of this condition, although stenosis of the pylorus due either to spasm or to spasm with muscular hypertrophy is a well-recognised condition in children. Recurrent pyloric spasm may well be a cause of cyclic vomiting in some children, but in the case now recorded it is quite evident from the subsidiary position occupied by the vomiting as well as from the physical signs no such cause would be acceptable as adequately explaining the symptoms. It is remarkable, however, that in the post-mortem examinations of such cases described in the literature gastro-intestinal lesions are frequent. Degeneration of glandular epithelium, small hæmorrhages, and shallow ulcers have been described in cases by Langmead [6]; necrotic changes in the mucous membrane of stomach and intestines by Crozier Griffiths [7]; dilatation of the stomach by Comby, and stenosed pylorus by Russell.

The general trend of opinion is inclined to the belief that cyclic vomiting is due to a deficient oxidation, particularly of fats, with the subsequent accumulation of oxybutyric acid and aceto-acetic acid in the blood and tissues. The acidosis is probably due to the action of intestinal toxins on the liver, while the symptoms themselves may be explained by the acid poisoning. It is one of the objects of this paper to combat this view and to emphasise as strongly as possible that the acidosis in itself had nothing to do with the onset of symptoms, and further, in general, acidosis may probably be disregarded as a cause of any abnormality in any disease, except, it may be, in diabetes.

A Chemical Study of the Patient.

In consequence of the discovery that the child excreted a large quantity of creatin during an attack, whereas a normal child of this age does not excrete creatin at all, a detailed study of the excretion of this substance was made. On the opposite page is given a table of figures obtained in this investigation.

The first prominent point to be noticed in the figures is that the child always excreted creatin. This is an abnormality in a child of 6, although it has been known for many

years that infants excrete creatin. It may be inferred, therefore, that the *cause of the recurrent illnesses was always present*, but that only at definite intervals did it rise to such proportions as to disturb many physiological activities. Incidentally, it may be mentioned that the excretion of creatin in the infant which appears to give way to the excretion of creatinin with age, is but one more example of the similarity of ontogenetic and phylogenetic development, for it has been shown by Meissner, and recently confirmed by Noel Paton,[8] that birds always excrete creatin while the mammalia always excrete creatinin.

The next point to be emphasised is the gradual rise of creatin in proportion to creatinin, before the onset of the attack. In fact, as early as June 27th (the attack started on July 2nd) it was evident from the abundance of the creatin excretion that the disturbing factor was approaching a maximum and that an attack was imminent. From the appearance and general condition of the child up to July 1st, it was impossible to imagine the approach of an exacerbation, and my suggestions, based upon the condition of the urine, as to the proximity of illness were not credibly received. It will be noticed, however, that during the height of the attack itself, whereas the creatinin excretion diminished from 0·28 grm. (average) to 0·165 grm. (average) per diem, the creatin excretion became remarkably high—e.g., 0·3 grm. per diem. Here, however, another factor comes in which I shall discuss at greater length later. The factor is the acidosis which accompanies the attack and which in itself is always related to a large excretion of creatin.

It may be well at this point to consider the facts concerning acidosis, involving the excretion of the acetone bodies, brought out in the above table. Unfortunately, none of the bodies β oxybutyric acid, aceto-acetic acid, nor acetone was estimated. Acetone was regularly tested for by Rothera's[9] method, and the intensity of the resulting permanganate colour together with the time of development gave one a rough idea of the relative quantity present.

The first point apparent is that acetonuria did not appear during the period of apparent good health. In this respect acetonuria is totally different from the creatinuria which, as stated above, was always present. The next point is that *acetone only appeared in the urine after the attack had been fully established.* It appears obvious, then, that acidosis is an effect rather than the cause of an attack. That this is the case is also evident from the following. At 3 P.M., July 4th—i.e., during the attack—the boy was given glucose (20 grm. to the ounce), together with soda-water, and by 9 A.M. July 5th he had taken 12 oz., which is equivalent to 240 grm. of glucose. The acidosis was stopped almost immediately, and by 3 P.M. July 5th certainly, and probably some hours before, no acetone was present in the urine, whereas the temperature did not return to normal for a further nine hours. Here again, then, there is an apparent independence of acidosis and symptoms. With the disappearance of the acidosis the creatin excretion became markedly lower, the creatinin excretion increased, and the $\frac{\text{creatin}}{\text{creatinin}}$ ratio sank from 2·13 to 0·45.

It still seemed possible that although the accumulation of acid bodies in the tissues was not directly responsible for

Table showing Excretion of Creatin in a Case of Cyclic Vomiting.

Date.	Creatinin in 10 c.c.	Creatin in 10 c.c.	Creatinin in 24 hours.	Creatin in 24 hours.	Ratio creatin, creatinin.	Acidosis.	Remarks.
June 4th	mgrm. 8·8	mgrm. 17·2	grm. —	grm. —	1·96	Abundant acetone.	Child ill. Temperature up to 104°.

[8] Journal of Physiology, vol. xxxix., p. 485, 1909-10.

[9] 5 c.c. urine + 3 grm. of $(NH_4)_2SO_4$ + 3 drops 5 per cent. sodium nitroprusside solution (freshly made) + 2 c.c. ammonia—acetone gives slowly developing permanganate colour.

the onset of symptoms, yet indirectly they might be masters of the situation in that their appearance just upset the balance in a complex which was evidently unstable, and, as is evident from the creatin excretion, was being constantly attacked by other deleterious forces. If this were the case, then acidosis, occurring during a period of quiescence, ought to be followed immediately by an attack of illness. On July 8th glucose and other carbohydrates were taken off the diet, which for the most part consisted of meat, casein-bread, and milk, and this was maintained until July 12th. Considerable quantities of acetone appeared in the urine, together with an increase of creatin, so that the creatin-creatinin ratio rose from 0·2 to 1. But in spite of the acidosis the child was perfectly well, the temperature and all other conditions being quite normal. This is conclusive evidence that acidosis in itself had nothing whatever to do with the symptoms of cyclic vomiting. To apply the term "acid intoxication" to such a condition would then be absolutely wrong and misleading.

One other point was tried. Although acidosis depends upon the absence of, or inability to metabolise, carbohydrates, it really means an incomplete oxidation of fatty acids. Was it possible that the child's power to deal with fatty acids was deficient? To test this he was given cod-liver-oil, and extra quantities of cream and bacon fat were added to his otherwise normal diet. He relished the fat and put on considerable weight at this time, and no acid bodies appeared in the urine. In other words, his power to metabolise fatty acids was perfectly normal so long as there was a sufficiency of glycogen in the liver.

What, then, is the cause of this recurrent vomiting? Unfortunately, the child left the hospital during a quiescent period and so it has been impossible to complete the investigation. From a consideration of the creatin excretion in a great number of pathological conditions (shortly to be published) I feel that the condition depends upon some intoxication in the portal area which is constantly acting. Thinking it might be a bacterial infection, Mr. F. W. Twort of the Brown Institute endeavoured to grow cultures from the child's blood taken during the height of an attack. The results were negative. The urine was also sterile. A positive result would have been interesting, but a negative result does not discredit the theory of a portal infection. In his Harvey lecture of 1906 Herter mentions cases of cyclic vomiting depending upon excessive intestinal putrefaction. I am strongly inclined to connect one of the facts discovered recently by Dale [10] and Barger in their investigations of the physiological actions of amines with this case of cyclic vomiting. They isolated considerable quantities of β-iminazo-ethylamine, the amine from histidine, from the wall of the intestine of the ox, and Dale and Laidlaw showed that this substance produced vomiting and all the poisoning effects of peptone (except altering the coagulability of the blood) and was an extremely potent poison. Quite recently Twort and I have isolated from the contents of the human intestine a bacillus which produces β-iminazo-ethylamine from histidine. An account of this isolation will be published shortly. It seems to me that this case of cyclic vomiting might depend on an excessive formation of this substance or of something of a similar nature in the wall of the intestine. It can be well imagined that an excessive absorption of this substance into the portal circulation would produce many [11] of the symptoms developed in the above-described case.

To sum up:—

1. The child was never normal because he always excreted creatin. The cause of the attacks was always at work.

2. The creatin excretion rose considerably several days before the attack, so that by the estimation of this substance it was possible to predict the onset of symptoms.

3. Acidosis had nothing whatever to do with the attack, but was only an episode like any other symptom. And this for the following reasons: (*a*) the child's power to metabolise fats was quite normal; (*b*) acidosis started after the onset of symptoms and cleared up, on giving glucose, before their abatement; and (*c*) a condition of acidosis for four days in a quiescent period was accompanied by no trace of ill-effect.

4. It is thought that the condition of recurrent vomiting is due to some intestinal intoxication which may or may not depend on bacteria. It is suggested that such a condition might depend upon an accumulation or excessive formation of β-iminazol-ethylamine in the intestinal wall.

[10] See various papers in Journal of Physiology from 1909 onwards.

[11] The effect of injecting β-iminazol-ethylamine into a cat by Dale and Laidlaw showed one great difference from this case of cyclic vomiting—viz., purging as contrasted with constipation.

Creatinuria and Acidosis.

Following upon the introduction of Folin's method of estimating creatin—a method which is easy and accurate—physiological research into creatin and creatinin metabolism has been very active of recent years, although the investigation of the behaviour of these substances under pathological conditions has not yet gained a clinical footing. There can be but little doubt, however, that in the near future they will be regarded as of some importance in diagnosis.

Unfortunately, the physiological part played by creatin and creatinin is still shrouded in mystery, although it appears probable, in view of the concurrence, in the main, of recent investigations, that at least the right line of attack is being followed up. The old theory that when muscle contracts creatin is liberated and converted to creatinin has been entirely given up. In 1908 [12] I endeavoured to show that the liver is the centre about which creatin metabolism plays, and that it would be by concentrating one's attack upon this organ that the problems associated with creatin would be made clear. It seems fair to say that nearly all recent investigators on this subject have taken this view, although, on the other hand, the hypothesis itself which I promulgated as explaining my facts is certainly not sufficient and is probably not correct in its details.

One of the observations which I published was that in cancer of the liver large quantities of creatin appeared in the urine, while in conditions like syphilitic liver, cirrhosis of the liver, and venous engorgement no creatin was excreted. I shall shortly publish further papers on this subject. At the present moment I wish to bring to notice another condition in which creatin is excreted—viz., in correlation with acetone formation, as illustrated by this case of cyclic vomiting. Since all recent work on acidosis indicates that the liver is the main, and probably the only, seat of β-oxybutyric and aceto-acetic acids, it is evident that to establish a constant relation between creatinuria and acidosis will involve an explanation of creatinuria which is associated with abnormal liver metabolism.

It is safe to generalise as regards the condition of acidosis that in such a condition either the body has no carbohydrates or else cannot make use of carbohydrate. Under such conditions the katabolism of fatty acids goes wrong, and with the excretion of β-oxybutyric and aceto-acetic acids much of the energy of the fatty acids is lost to the body. Various observers have noticed that creatin is sometimes found associated with acetone in urine, but to Cathcart [13] is due the credit of having worked out this subject and shown that absence of carbohydrate from the diet, or inability to use carbohydrate as in diabetes, involves an excretion of creatin. Since acidosis depends on absence of carbohydrate, and since creatinuria also depends on absence of carbohydrate, it seems legitimate to associate creatin with carbohydrate in its normal function in the body. Yet such an inference, I think, would be wrong. This is not the occasion on which I can discuss this matter, but I should just like to point out that the creatin excreted in this case of cyclic vomiting obviously results from *two* causes. In the first place, the child always excretes creatin, even when his carbohydrate and fat metabolism were normal—i.e., at a time when he was quite well, putting on weight quickly, eating a sufficiency of carbohydrate, and excreting no acetone bodies. Secondly, with the appearance of acidosis the creatin excretion was markedly increased, only to diminish greatly on the addition of glucose to the diet. I think one can only generalise to the extent that in both cases the creatin excretion was due to a liver abnormality—in the first case due to the action of some toxin, the potency of which periodically became so pronounced as to make the child very ill, and in the second case depending upon, or only associated with, the aberrant fatty acid metabolism due to lack of glycogen in the liver cells. The question then arises as to whether the cause of creatin excretion in diabetes is identical with that which is associated with the creatin excretion of inanition or deficiency of carbohydrate, or whether some other cause, as in cyclic vomiting, is present. Using an

[12] Journal of Physiology, vol. xxxvi., p. 447.

[13] Ibid., vol. xxxix., p. 311.

adequate method of detecting acetone—i.e., Rothera's sodium nitro-prusside reaction—I have been struck by the almost constant appearance of this substance in the urine of diabetic patients, and I think it probable that only one cause—the abnormality of the fat metabolism of the liver depending upon deficient use of carbohydrate—is present in such cases.

From the examination of large numbers of pathological urines, I think it can be safely stated that *all cases of acetonuria are accompanied by creatinuria, while the reverse is certainly not true.* The fact that this relation is not reciprocal should of itself make one hesitate to associate creatin directly with carbohydrate metabolism. Incidentally, I should like to add that the creatinuria of cancer of the liver is not associated with acidosis, although, it may be, of course, if the patient is starving.

Whereas the physiological chemistry of acidosis has rapidly been elucidated by the work of physiologists during the past decade, that of creatin and creatinin stands resistant to all efforts. The distinctive feature about these latter two substances is the methylated nitrogen which might conceivably arise in one of two ways: (1) by destruction of the protein molecule; and (2) by the methylation of the N group of some intermediate product of metabolism. Present knowledge is decidedly against the first explanation, for no methyl-imido (CH_3–NH) group has ever yet been isolated or distinguished in protein. However, the chemistry of the molecular grouping of protein is by no means complete yet, and it would not be surprising if this grouping were discovered. As regards the methylation of the nitrogen atom, it is a well-recognised means adopted by the body for rendering harmful substances innocuous—e.g., tellurium is excreted as methyl telluride; and pyridin is excreted as methyl-pyridyl ammonium hydroxide $OHCH_3$–NC_6H_5. With this idea Jaffé[14] fed rabbits on glycocyamin (guanidin acetic acid) and found, in consequence, that the excretion of creatin (methyl guanidin acetic acid) was increased. I think, however, that these results should be accepted with great caution, for during the experiments the rabbits were ill and developed diarrhœa, and I have noticed that a rabbit with diarrhœa always excretes considerable quantities of creatin. From the methylation point of view, creatin is chemically related to arginin, since they both contain the guanidin grouping $C(=NH)(NH_2)_2$, but the nitrogen of ingested arginin is nearly all excreted as urea. Again, both creatinin and histidin contain the imidazol ring, yet there is no evidence that these substances are physiologically related in the body.

With acetonuria, on the other hand, the matter stands very different. Although it seems probable that the formation of acetone itself has no significance, yet it is constantly excreted in acidosis, in amounts which run parallel to the really significant substance β-oxybutyric acid (Gunnar Forssner).[15] Even the normal person can only partially metabolise acetone, whereas ingested β-oxybutyric acid is completely used, so that it is probable that the formation of acetone in acidosis is a chance occurrence of no physiological significance. Its importance lies in the ease with which it is detected. The study of acidosis in diabetes has been the basis of splendid work performed by Baer and Blum, Schwarz, Knoop, Friedmann,[16] and other continental researchers. By noticing the influence of all manner of ingested fatty acids on the excretion of β-oxybutyric acid in diabetics, they have succeeded in elucidating one of the two important known chemical changes which take place in fatty acid katabolism—namely, their oxidation at the β, δ, &c., carbon atoms. Similar work has been done on alkaptonuric patients excreting homogentisic acid, and from this considerable information as to the breaking down of aromatic substances in the body has been gained. All these results have been controlled by Embden,[17] who perfused livers with different acids and estimated the β-oxybutyric acid formed. Although but little of such work has been done in this country, the other side of fatty acid metabolism—namely, the introduction of unsaturated linkages by the liver—has been entirely developed by English workers—Leathes[18] and his collaborators, particularly Hartley,[19] and at Cambridge, Mottram.[20] Gradually are we beginning to see why unsaturated acids like oleic and erucic acids do not increase the acidosis of a diabetic patient, while stearic, palmitic acid, and, better still, butyric acid do so. Also, how a protein molecule can be regarded from an acidosis point of view as being composed of two parts—one part represented by leucine and tyrosine, which on being denitrified increases the excretion of β-oxybutyric acid in the diabetic patient, and the other portion represented by alanine, valine, and glycocoll, which exerts an antiketonic effect, and reduces the β-oxybutyric acid of artificially induced acidosis. From which effect it seems legitimate to assume these latter substances are either built up into a carbohydrate molecule or into some intermediate breakdown product of carbohydrate metabolism.

One other point, and the most important from the clinical point of view—the part played by acidosis in regard to symptoms—remains for brief consideration. Ever since Stadelmann, Naunyn, and Magnus Levy[21] insisted on their importance in diabetic coma, the medical mind has assigned to the presence of β oxybutyric acid and the acetone bodies in the organism an importance which is nothing short of ludicrous. No matter what the symptoms are, if acetone is found in the urine, it appears customary to describe the case as one of acid intoxication. It seems necessary to mention that even in diabetic coma it is by no means a fully settled question whether the symptoms are *directly* due to the acid bodies. The comparative failure of the alkali treatment; the vagarious way in which some diabetic patients excrete large quantities of β-oxybutyric acid for years without symptoms; the absence of any change in the alkalinity of the blood plasma in such patients, whereas in artificial acidosis in animals produced by the ingestion of acids there is a slight but definite decrease in alkalinity; the occurrence of dyspnœic coma in uræmia, and other non-diabetic cases; these points and several others can be urged against the theory of direct relation between the acids formed in diabetes and coma. Besides, the other condition accompanying acidosis—absence of, or inability to use, carbohydrate in the liver—does not appear to have been sufficiently considered as a possible factor in the onset of diabetic coma. Undoubtedly one of the most important functions of the liver is to neutralise poisonous substances which may be either absorbed from the intestine or be formed in the metabolic changes of the body. The excretion of toxic substances such as camphor, chloral, phenol, and skatol, as compounds of glycuronic acid, makes it evident that this "Entgiftung" property of the liver depends to a large extent on carbohydrates. Other evidence in the same direction was obtained by Hildebrandt,[22] who showed that a lethal dose of thymotin piperidide loses its effect if glucose, cane sugar, maltose, or to a less degree levulose, was given at the same time. May it not well be that in all cases of severe symptoms accompanying acidosis, and even in diabetic coma itself, one of the most important factors is the absence of glycogen in the liver cells, with a corresponding diminution in poison-neutralising effect, thus allowing the diffusion of intestinal and toxic substances other than acids throughout the organism? Certainly the method of combating acidosis of conditions other than diabetics by large quantities of glucose seems to me to be more scientific and more likely to lead to beneficial results than the giving of alkalies. By this means one is obviously tackling the condition nearer its source than when simply attempting to neutralise an already fully neutralised series of acids which are probably of no more importance than some of the other known chemical abnormalities

—such as the presence of creatin—which accompany this condition. For even if the causal connexion between acidosis and diabetic coma is accepted, there can be but little doubt that the acidosis as such, accompanying fever, gastro-enteritis, delayed chloroform poisoning, and cyclic vomiting, and many other conditions, is never of symptomatic significance. In other words, the term acid-intoxication, in the real sense of the word, applied to these conditions is a misnomer. The quantities of β oxybutyric acid and other acetone bodies excreted in these conditions are small—i.e., 10 to 15 grm. at the most—compared with the quantities excreted in diabetes, e.g., one of Magnus Levy's cases excreted 160 grm. per diem, and it is difficult to see how they could possibly produce symptoms. As regards the case above described, it has been seen that acidosis was merely a symptom and had nothing whatever to do with the attacks of cyclic vomiting.

THE PHYSIOLOGICAL IDEAL IN THE ARTIFICIAL FEEDING OF INFANTS.

BY J. SNOWMAN, M.D. BRUX., M.R.C.P. LOND.

IT was said by Oliver Wendell Holmes that a pair of substantial mammary glands have the advantage over the two hemispheres of the most learned professor's brain in the art of compounding a nutritious fluid for infants. Since the enunciation of this aphorism the problem of infant feeding has increased enormously in urgency, but, unfortunately, much of the study devoted to the subject has only served to create difficulties and introduce complexity.

When an infant is submitted to artificial feeding the three most important questions which demand categorical replies concern (1) the quality of the food, (2) its quantity, and (3) the frequency of its administration. For the sake of convenience we will deal first with the two latter questions.

The quantity of food required by a healthy infant is usually ascertained from tables which exist in abundance both in medical and popular literature. These tables are constructed according to age-periods—a method which is physiologically unsound. There is no correspondence between age statistics and nutritional requirements. An infant requires food for purposes of growth, maintenance of body temperature, and as a source of energy for the performance of its vital functions. The amount required varies, not with its age, but with its weight and surface area. It is at once obvious that we cannot rationally satisfy the vital process of two healthy babies according to infant-feeding tables when one weighs 6½ lb. and the other 10 lb. at the same age.

A practical method of adjusting the infant-feeding tables according to weight would be to estimate exactly how much milk healthy infants of varying weights draw from the breast at each feed. The following may be taken as a fair average:—

Weight of infant.	Amount of feed.	Weight of infant.	Amount of feed.
6½ lb.	1½ oz.	15 lb.	4½ ,,
8½ ,,	2½ ,,	17 ,,	5½ ,,
11 ,,	3 ,,	19 ,,	7 ,,
13 ,,	3½ ,,		

As these are the quantities prescribed by Nature they stand in no need of further justification. But we may inquire whether these figures possess any rational significance. The scientific examination of these figures reveals the striking fact that four-fifths of the amount of food consumed by the healthy infant at the maternal breast corresponds precisely to the physical expenditure of the infant, and the other fifth is, therefore, employed in growth. This calculation is arrived at quite simply if we appreciate certain cardinal principles. The most important of these concerns the fact that the combustion of an infant's food within its tissues produces heat. An infant, in proportion to its weight, generates three times as much heat as an adult, because the surface area of an infant is, proportionately to its weight, nearly three times as great as that of an adult. We must be able to estimate the quantity of heat lost before we can assign the amount of food required to cover this loss, and in addition we must, of course, know how much heat the combustion of the food will supply. All these factors have now been accurately measured. Experiment shows that the amount of heat given off per diem by an adult equals 10 calories for every pound of his weight. We have already seen that an infant's loss of heat is thrice that of an adult, comparing weight for weight, therefore 30 calories per pound weight represent an infant's loss of heat. Consequently the average baby, weighing 7 lb. at birth, will lose 210 calories of heat daily. This must be replaced by food of adequate calorific power, and beyond this a supply sufficient for growth must be provided. This additional amount corresponds to one-fifth of the quantity imbibed by a healthy infant from the breast. Therefore the total amount of food required by an infant must represent the value of some 250 calories.

What is the practical value of this apparently theoretical calculation? This is at once realised when we remember that the average baby obtains from the mother within the first fortnight of its existence a daily amount of about 16 oz., and that the total combustion of 16 oz. of human milk produces 250 calories of heat. Thus the remarkable fact is clearly demonstrated that Nature provides for the infant just that sufficiency of food which will make good all its heat loss, and supply in addition an adequate pabulum for growth.

The daily amount of an infant's food bears a constant relation to the frequency of the feeds, because the whole quantity must be divided into portions corresponding to the capacity of the stomach. The amount which an infant's stomach can comfortably contain depends upon its weight; thus in a 7 lb. baby this will be 1½ oz., in a 14 lb. baby it will be 3½ oz. As a 7 lb. baby requires 16 oz. per diem this amount must be subdivided into 11 feeds. A 14 lb. baby consumes about 28 oz. per diem, and therefore eight feeds will be the appropriate number for it. It is noteworthy that the intervals of feeding, as determined in this way, correspond with the rise and fall of the lacteal tide in the human breasts, and that they also correspond with the periods required for the emptying of the infant's stomach.

Having thus seen that Nature's instinctive method of infant-feeding proceeds on a system which is confirmed by the strictest scientific inquiry, we are in a position to apply these principles to the qualitative artificial feeding of infants. If we accept cow's milk as the only practicable substitute for human milk, it would be a very simple matter to compare the caloric value of the two kinds of milk and give that amount of cow's milk which will yield the necessary number of calories. This calculation is very easy because the caloric value of cow's milk is greater than that of human milk in the proportion of 7 to 5. But an infant is not a calorimeter and the arrangement of its artificial diet cannot be conducted on this mathematical plan. The great factor of digestibility must be reckoned with, and this consideration involves an accurate knowledge of the difference in constitution between cow's milk and human milk. Artificial infant-feeding becomes a fine art when cow's milk is so modified as to resemble the constituents of human milk both in kind and in degree. The task is a complex one because a comparison of the analysis of the two milks shows that much readjustment is required. The urgency for this is emphasised by the almost universal experience that cow's milk upsets babies unless it is modified in some way or other.

The problem to be solved is postulated immediately we arrange the analyses of cow's and human milk in juxtaposition. Although these analyses vary from each other they all agree in displaying the essential differences between the two milks. The following analyses may be submitted:—

Cow's milk.					Human milk.				
Casein.	Lact-albumin.	Sugar.	Fat.	Salts.	Casein.	Lact-albumin.	Sugar.	Fat.	Salts.
3	·3	4·4	3·4	·7 (Randnitz)	·6–1	·5	6·4	3·4	·14–·28
2·5–3·7	·5–1	4·4	3·5–4	·6 (Cautley)	·6–1·3	·5–1·2	6–7	3–4	·2
3·25	·75	4	3·5	— (Still)	·6	1·4	7	3·5	—
2·7–3	·2–·3	—	—	— (Bergell)	·8	·6	—	—	—

All authorities agree in ascribing the same percentage of fat to both human and cow's milk. They also agree that human milk contains about 2 per cent. more sugar than cow's milk, and that the latter contains at least three times as many saline constituents as human milk. But there are some variations in regard to the proportional percentages of casein and lactalbumin. Notwithstanding these variations, however, one outstanding fact is brought into bold relief—i.e., that the proteid content of human milk consists very largely of lactalbumin, whereas the proteid of cow's milk is almost entirely casein. As we must credit Nature with the faculty of providing what is physiologically the most appropriate nutriment, it follows that our artificial diet for infants must contain a greater amount of lactalbumin than is present in cow's milk, or in other words, must contain as much lactalbumin as is present in human milk. To realise this is one of the fundamental conditions for success in the artificial feeding of infants, and undoubtedly one of the great causes for failure is the fact that in the milk modification usually recommended this lactalbumin is replaced by casein. The majority of text-books teach that cow's milk should be diluted until its proteid content approximates to the proteid content of human milk. The reason advanced for this is the indigestibility of the casein of cow's milk, but it is obvious that dilution only makes the proteids of cow's milk resemble the proteids of human milk arithmetically but not physiologically. It is not because a milk has a total proteid content equal to human milk that it is suitable for infant-feeding. It might just as well be argued that a milk with a total solid content equal to that of human milk constituted a suitable food for an infant.

The solution of the difficulty involved herein is to be found in correlating the two facts that (1) cow's milk casein is acknowledged as the great obstacle to infantile digestion; and (2) that Nature provides a large proportion of lactalbumin in human milk. Now it is clear that a considerable dilution of cow's milk can reduce its quantity of casein to that of human milk. According to the figures given by most authorities this would require a very much greater dilution than is the usual practice. But it is also clear that no manipulation of cow's milk can render it equal to human milk in lactalbumin content. As the cow's milk is diluted so the lactalbumin begins to vanish, and even if it is not diluted at all it falls far short of the proportion required.

It has, of course, been recognised that this deficiency in lactalbumin is a serious blemish on the customary methods of milk modification. Hitherto there has been one palliative available which consists in diluting the milk with whey—i.e., a solution of lactalbumin, sugar, and salts. The method succeeds in providing nutriment containing as much lactalbumin as cow's milk possesses. The use of whey, however, only meets the difficulty very partially, because, in the first place, it cannot possibly supply Nature's proportion of lactalbumin, and, secondly, the domestic preparation of whey is troublesome, the product is often a decided failure. In addition to this, German observers have lately drawn attention to cases of severe gastro-enteritis accompanied by signs of general intoxication as a result of the use of whey in infant-feeding. Indeed, it has been found that a milk mixture containing the casein of human milk and the whey of cow's milk produced similar results, thus clearly fixing the responsibility on the whey constituent of the mixture.

This line of reasoning enforces the conviction that the addition of pure lactalbumin to the milk mixtures of hand-fed infants is an indispensable requirement in order to guarantee the success of artificial feeding. It is just as illogical to deprive an infant of its lactalbumin as it is to deprive it of its sugar. To supplement the inadequate amount of lactalbumin contained in the usual milk mixtures by an excess of casein is to throw an undue burden on the physiology of gastric digestion. We need but recall the series of changes to which casein is subject in the stomach and intestines before it is absorbed and compare them with the physical ease with which soluble albumin is absorbed to understand that casein can never be an appropriate substitute for lactalbumin.

Modern research, moreover, suggests that it is the abundance of lactalbumin present in human milk which makes its casein digestible, and that cow's milk casein is indigestible because of the paucity of lactalbumin with which it is associated. Consequently, the crucial distinction between the digestibility of cow's milk and human milk rests with the difference in lactalbumin content. The explanation of this circumstance follows from certain experimental investigations made on the physical state of solutions. Attention has been drawn to the condition of "colloidal solution," such as is formed by gelatin, gum, or other "colloid" bodies. A peculiarity of these colloidal solutions is that they cannot be precipitated by an acid, base or salt, but these solutions when dried can be re-dissolved. It has further been shown that many metals—e.g., silver, gold, mercury—can be prepared in the form of colloids, but when these are dissolved the solutions are precipitated by the action of an acid, base or salt. Moreover, these solutions when dried do not re-dissolve. It is obvious, therefore, that there are two classes of colloids with differing physical properties. The former group is known as "reversible colloids," the latter as "irreversible colloids." Further experiment revealed the fact that the addition of a small quantity of solution of gelatin to a solution of colloidal silver protected the latter solution from precipitation, and enabled the solution after drying to become re-dissolved. It is now known as a physical fact that a reversible colloid protects an irreversible colloid from precipitation or coagulation. The importance of all this centres in the circumstance that *casein is an irreversible coagulating colloid*, whereas *lactalbumin is a reversible or protecting colloid*. Human milk thus contains an excess of protective colloid, and therefore its casein forms a fine soft coagulum, in contrast to the firm bulky curd of cow's milk.

Thus there accumulates an abundance of evidence, decisive of the claim for lactalbumin in infant-feeding. As lactalbumin is now procurable in the form of a neutral soluble substance in powder form, there is ample opportunity for its adoption in practice. This substance, termed albulactin, lends itself to a very ready demonstration of its effects if a weak solution be added in a test-tube to pure milk and then acidified with diluted acetic acid, and the result be compared with the contents of a test-tube of pure milk without albulactin to which dilute acetic acid has been added. In the former case the precipitate obtained is soft, flocculent, and consists of minute particles; in the latter case the precipitate is the ordinary thick, firm, and tough curd. Further, if this former precipitate is compared with the result yielded by human milk to which dilute acetic acid has been added they will be absolutely indistinguishable from each other. This, however, is not mere test-tube experimentation, for it is confirmed by clinical experience. Dr. Kamnitzer and Dr. Cassell have recorded a series of cases of infant-feeding wherein this effect of albulactin has been verified by syphoning off the stomach contents during the process of digestion. They compare the material drawn off to small-grained oatmeal soup contrasting very markedly with the thick and dense curd formation which characterises the digestion of cow's milk in the infant's stomach. As collateral evidence one may adduce the observation frequently made by experienced nurses, that the stools of infants taking milk modified with albulactin are practically identical in appearance with those of breast-fed infants.

The amount of albulactin which should be added to the milk mixture in order to secure these physiological benefits should correspond with the amount of lactalbumin present in human milk. Some observers put this as high as 1·4 per cent., others as low as 0·5 per cent., but for practical purposes an addition of 3 grains to each ounce of the milk mixture is perfectly satisfactory. Having made this provision for the supply of the lactalbumin one may dilute the cow's milk so as to reduce the casein in the mixture to the percentage in which it exists in human milk. This is merely a matter of manipulating figures, but in view of the uncertainty of figures and of some recent criticism to which the whole subject of casein has been submitted, it is doubtful whether this extreme reduction in casein content is required.

Professor Budin of Paris claims success for feeding infants on undiluted cow's milk which has been fully sterilised. It is stated that the complete sterilisation alters the casein in such a way as to prevent the formation of tough curds. A new method of feeding in case of gastro-enteritis and toxæmia of infants by means of "casein" milk has lately secured extensive trial in Germany. This milk contains 3·5 per cent. of casein, and only 1–1·5 per cent. of sugar, but the casein is presented in such a way that the development of indigestible curds is prevented. It probably exists in this milk in the form of casein lactate.

From yet another source there comes corroborative evidence

that casein has been unduly incriminated in the production of digestive disturbances in infants. From time immemorial we have been accustomed to scrutinise the stools of infants, and we have pointed to the white masses as testimony of casein indigestion. Some authorities have lately denied the truth of this inference, and maintain that these masses do not consist of casein but of fat. Some analyses are said to have shown that they contain fatty acids and soap only. Other analyses certainly do reveal the presence of proteid, but the suggestion is made that this probably comes from the intestinal secretion. Indeed, Ludwig Meyer states that these so-called casein curds are even found in the stools of infants fed on whey. A keen controversy is in progress in regard to this matter, but it is quite obvious that the truth lies midway between the extreme views of the opponents, for it is well known that casein entangles a large proportion of fat in its meshes as it clots. If the clot happens to be tough, it will resist the action of the digestive juices; the fat in its interior will not be acted on by the pancreatic secretion, and hence the appearance in the stools of more or less unaltered fat. There is no doubt that large curds owe their size to their association with fat. Simple casein curd without any fat is never bulky, neither is it leathery and tenacious.

These observations also direct our attention to the existence of fat indigestion. It would be rash to adopt the view of those who are beginning to ascribe to the fat of cow's milk the main responsibility for infantile indigestion, but we cannot disguise from ourselves the fact that there are important differences between the fat of human milk and of cow's milk. The fat of human milk is comparatively rich in olein, which is an easily digested substance, whereas stearin and palmitin predominate in cow's milk fat, and these require much more digestive effort. The fat of human milk has a higher iodine value than that of cow's milk, and it also possesses a lower melting point. When cream is used to supply deficiency in fat the infant is often provided with some preservative which may prove detrimental. So far we are unaware of any plan to eliminate fat indigestion as has been achieved in the case of casein indigestion. But the very fact that we can banish casein indigestion and permit an infant to feed with impunity on a somewhat larger proportion thereof than Nature dictates, intimates to us that our dilution of the cow's milk need not go so far as to make it unduly poor in fat, and thus there will be no need to add cream to the final mixture. There is reason to believe that an excess of really digestible casein will satisfactorily supplement the deficiency in fat as long as it does not fall below 2 per cent. If the fat is reduced to less than 1 per cent. the infant becomes hungry, notwithstanding an abundance of proteids. It is not possible to be dogmatic on this question of fat in infant feeding, because current scientific opinion thereon is in a state of fluctuation, but it is undoubtedly wrong to assume that the usual mixture containing equal parts of milk and water requires the addition of cream. Provided that the casein in such a mixture is really digestible the addition of cream is in ordinary circumstances quite unnecessary.

The practical outcome of the foregoing remarks resolves itself into a strong claim for a routine milk mixture which consists of equal parts of milk and water, with the addition of three grains of albulactin (lactalbumin) to each ounce of the mixture and of an appropriate quantity of sugar. Although this mixture contains more casein than human milk, this excess is justified by the presence of lactalbumin, which protects it from the formation of tough curds, and it likewise also compensates for the fact that the fat is not up to the human standard in quantity. This mixture of equal parts of milk and water should not be given to infants for the first fortnight; they should be started with 2 parts of water to 1 of milk. The proportion may then be raised to 3 parts of water to 2 of milk, and at the end of the second month the normal healthy infant will be quite prepared to digest equal parts of milk and water, with the appropriate addition of lactalbumin and sugar. The amount of each feed must be regulated according to the weight of the infant, as explained earlier in this paper.

The use of lactalbumin in the artificial feeding of infants is a comparatively new procedure. The recorded observations already made with it convince one that its action in the modification of cow's milk promises to supersede all the other devices which are in vogue for making such milk suitable for infants. When a new-born infant is started upon its career of hand feeding the practitioner is always anxious as to whether the bottle will agree. My own observations have impressed me very firmly with the conviction that these anxieties may be dispelled when the milk is modified with soluble lactalbumin. It gives a sense of security which is otherwise only felt when breast feeding is being employed. Previously in my own practice, if an infant showed any signs of dyspeptic discomfort in its early days of artificial feeding it usually meant that there would be much ringing of the changes before a suitable milk mixture could be found. But after having recourse to milk modification by means of lactalbumin it soon became evident that this method bore the palm, and that it is preferable to and more reliable than the use of citrated milk, peptonised milk, cream and whey feeding, and all other plans which have been adopted to meet the frailty of infantile digestion.

The following instances will illustrate the type of case upon which my view of this method of milk modification has been founded.

CASE 1.—Child born April, 1909. The mother a somewhat elderly primipara, in whom the establishment of lactation took longer than usual. The infant, after struggling in vain with the breasts for three or four days, apparently felt the delusion and disappointment so keenly that it absolutely refused to make any further attempts when the belated milk actually arrived. A milk mixture (1 part cow's milk to 2 of water) was given with all due precaution; this resulted in the production of intense colic and flatulence. The infant cried literally for hours at a stretch, causing a hernia to protrude, and there was vomiting of the usual thick curds. The milk was diluted 1 to 3 and citrate of soda added; the pain appeared to be less; the vomiting continued, but the curds were less dense, and diarrhœa supervened. At the end of the first week the infant had dropped in weight from 7 lb. 2 oz. to 6 lb. 12 oz.; its face indicated distress, and the whole outlook was unpromising, as the greater part of the night was still occupied by the infant's moaning. I then left off the citrate of soda and added 5 grains of albulactin to each ounce-and-a-half feed of cow's milk diluted as before 1 to 3. The most striking effect was the cessation of the colic, for the infant then experienced its first comfortable day, the vomiting followed suit, and the second week registered a gain of 2 oz. In the third week the strength of the milk mixture was increased to 1 to 2, and as development was proceeding apace this strength was progressively increased to equal parts of milk and water, which the infant digested most satisfactorily at the age of 10 weeks, its weight then being 10½ lb.

CASE 2.—This baby was born in July, 1909, and was the second child of parents whose first child had died a year previously in a convulsive seizure consequent upon digestive disorder. The infant was only of eight months' gestation, but weighed 6 lb. at birth. The mother was unable to suckle and the child was fed from the first with humanised milk delivered to the house in the Soxhlet outfit. On the sixth day there was definite jaundice and then diarrhœa supervened with an eczematous condition of the buttocks. Half-grain doses of grey powder were given daily for three days without improvement, and as the weight had then fallen to 5 lb. 6 oz. a change of food was made to a dilute whey and cream mixture. The diarrhœa certainly diminished, but this mixture was promptly vomited after each feed. During the second week the infant lost another 4 ounces, and a somewhat widespread outbreak of seborrhœa appeared on the fourteenth day. I then fed the infant for two days on a 1 per cent. solution of albulactin with milk sugar, which was well retained. The next step was to fortify this solution with cow's milk, beginning with two teaspoonfuls to the ounce, gradually increasing the quantity of cow's milk, as the mixture appeared to agree perfectly. There were no further symptoms of dyspepsia, and when the child was a month old its weight was again 6 lb. The further progress of the case was excellent, and the child weighed in January, 1911, 14½ lb.

CASE 3.—This infant was 3½ months old when he came under my care in September, 1910. He was being breast-fed, but for the last few weeks the weight had been fluctuating between 10 and 10½ lb. There were great distress from colic, very frequent sickness, and obstinate constipation. It was clear that this was one of those somewhat rare cases where the mother's milk was not agreeing. A change of diet under these circumstances is often a perilous undertaking, but I ventured, with some confidence, on a mixture consisting of equal parts of cow's milk and water (1½ oz. of each) with the addition of 10 gr. of albulactin to each feed. The result was perfectly gratifying, no further indication of dyspepsia ever manifested itself. The whining and moaning baby became transformed into a picture of contentment, he began to thrive again immediately, and while under observation there was a steady increase in weight of some 4 oz. per week.

To advise a change from human milk to cow's milk is very rarely required in the feeding of infants. It constitutes the exception which emphasises the rule that the breast must dominate in the realms of infant-feeding. No artifice of scientific modification can compare with the human secretion, and if it be true that the composition of milk changes while it is actually being withdrawn by the infant from the breast, so that the fore milk differs in its fat and casein proportions from the subsequent milk, it is evident that "percentage" feeding, calculated with mathematical accuracy, is a fallacious imitation of Nature. No ingenuity of contrivance can provide an infant with a "course" of food of varying composition such as it apparently obtains from the breast. But though it be vain to attempt

to follow Nature to the accuracy of decimal points, it nevertheless does behove us to adhere to the broad principles of imitation. We cannot pretend to maintain these principles as long as we ignore the existence of lactalbumin and act as if it were identical with casein. It is to be hoped that the attention which has been drawn to this anomaly will contribute towards the removal of a serious obstacle in the successful management of infant-feeding. The few cases quoted above only refer to the adoption of lactalbumin modification after other methods had failed, but the ideal in this respect will not be attained until it is recognised that the nutritive function of lactalbumin in milk ought to be given its opportunity long before mischief has set in. On chemical, physiological, and clinical grounds lactalbumin demands a permanent position in all cow's-milk mixtures intended for infant use.

Shoot-up-Hill, N.W.

SUCCESS OR FAILURE IN ELECTRO-THERAPY: A CONSIDERATION OF SOME OF THE CAUSES.[1]

BY SAMUEL SLOAN, M.D. GLASG.,

PRESIDENT OF THE ELECTRO-THERAPEUTICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE DURING 1909-10; EXAMINER IN MIDWIFERY AND DISEASES OF WOMEN TO THE UNIVERSITY OF GLASGOW.

THIS is the tenth year since the foundation of the British Electro-Therapeutical Society, the parent of the present Electro-Therapeutical Section of the Royal Society of Medicine, and it seems to me a fitting opportunity to review the progress of electro-therapeutics during that time. Electro-therapy now has no need to fear the sneers of the profession. At the present day it is more in danger of being made the spoilt child of medicine, for it is admitted even by those who are not working in this department that no specialty has made more advance in recent years or is pursued on more strictly scientific lines.

I shall not attempt to give a *résumé* of the general progress of electro-therapeutics since the foundation of our society, but shall confine myself to what is strictly personal, and attempt to give briefly a record of some of the experience I have myself gained during these years, in so far as it may be helpful towards securing success in the future.

If I had been asked, affer one year's experience of high-frequency treatment, what I really thought of it I should have had to confess that I had some difficulty in answering the question. My work had not been so successful as I had anticipated. I had not even then realised the possibilities of the treatment. By that time I had acquired so much experience of low-tension currents that I was perhaps hard to please. Now I have no hesitation in saying that I would be seriously handicapped in the struggle with disease without the whole of my electric plant at my command. I have had many failures in the past, but I have endeavoured to make these failures milestones on the road to success, and I am feeling now such an amount of confidence in the therapeutic effects of electric currents that I start treatment in new cases with an assurance of success which I formerly could not have believed possible.

Wherein, then, is this confidence? This is the subject of my paper. In the first place let me emphasise the importance of a correct diagnosis in each case. This does not mean merely determining the name of the disease: it means obtaining a complete grasp of the patient's condition—why is he ill; what prevents him from getting well; what, if any, cause is still in operation? Indeed, I am realising more and more that the successful electro-therapeutist must be first of all a skilled physician with a wide experience of men and women in health and in disease; for it is a diagnosis not of the disease but of the patient which is all-important. Again, many failures in electro-therapy, I feel sure, are due to neglect in the diagnosis, not of the disease but of the cause. Take a case of headache, for instance. How difficult it is we all know to cure many of these even electro-therapeutically, largely because the discovery of the cause so often baffles us. Though there are many causes of headaches, these may for all practical purposes be considered as two only—namely, toxic and ocular. Let this be borne in mind and the cure is much simplified. If toxic, is the sepsis oral, tonsillitic, intestinal, uterine, or urinary? No permanent improvement can be effected till this is determined. Not the headache, therefore, must be treated in these cases, but the sepsis, and, except when the dentist is required, this can usually be to no small extent carried out electrically. If, again, on the removal of the sepsis medicinally or electrically the headache should persist, as is not at all unlikely, whether it be due to cerebral congestion or to peripheral neuritis, we have admirable means in our electric armamentaria to combat it. Oculists inform us that if the headache is ocular only the pain will be found absent on waking in the morning, will come on early in the day, and steadily increase till evening. Toxic headaches, on the other hand, are worst in the morning and get better as the day goes on, owing to the elimination of the toxins by exercise and fresh air. Of course, these two causes may be combined and often are, the headache being present in the early morning and remaining all day. Suitable glasses will at once remove the ocular cause and make the management of the case a more simple matter electrically. The same may be said of insomnia; but here we have a less simple origin. The psychic element enters largely into the etiology of this distressing complaint. Therefore the greater is the importance of a minute inquiry as to the whole life of the patient. Is the cause idleness, alcohol, emotional excess, or undue nerve strain? Once remove the cause or causes, however, and, if sound sleep does not follow, we have an assured means for its cure. At least this is my experience of treatment by faradisation of the brain, and even by auto-condensation.

Again, another cause of failure in electro-therapeutics, besides the failure to detect the cause, is that the electric treatment is begun before the patient is ready for it. He has come for this kind of treatment and will be disappointed if it is not started at once. Some preliminary treatment, however, is usually needed. Or, again, he is too weak or his work is too strenuous, or coming for it would involve an amount of fatigue which might not only prevent it from helping but even make it capable of doing injury. Anything, indeed, which is capable of benefiting in suitable cases, and when suitably administered, is equally capable of injuring under different conditions. This may almost be taken as an axiom, but I fear that in electro-therapy it is too frequently forgotten.

I have referred to the fact that, even after the removal of all the causes of disease, it by no means follows that all the symptoms will disappear. I had a few months ago an illustration of this. A gentleman called upon me for a certificate that he was no longer fit for his occupation. He was, and had been for many years, an accountant in an insurance office, and was finding it impossible to keep his brain in working order. His idea was that an outdoor occupation, such as inspector of agents, was all he was now fit for. I said I was not prepared to agree with him without some investigation of his case. I found upon examination that he was suffering from oral sepsis, gastric disturbance, and general ill-health, and I advised first the removal of all diseased stumps, then a tonic and a fairly long holiday. He felt so much better on his returning in a few weeks that he resumed his old work with the expectation of being able to continue it, but in a very short time his former condition returned and he was quite unable again for any brain-work. I then began the application of faradisation to the brain and promised to make him in a short time perfectly fit for his usual occupation. After a course of this, during which he remained at his ordinary employment, he declared himself quite well and able to manage his work with his former ease. Coming to me afterwards, he said that having been busy of late with the annual balancing of accounts, and having been working for the two previous weeks daily from 9 A.M. to 10 P.M., he was fearing another breakdown. I resumed the treatment for a few days, and so enabled him to tackle successfully the extra work till it was finished. In alcoholic cases, again, there is sure to be failure if treatment is undertaken without a period of probation and preparation. Total abstinence should be enjoined or only small quantities of a light claret or lager beer allowed, with perhaps a mild course of some saline. With these preliminaries a course of electro-therapy may be begun with reasonable expectation of success. Even in serious organic disease, where cure is impossible, I

[1] Read at a meeting of the Electro-therapeutical Section of the Royal Society of Medicine on April 21st, 1911.

have known life prolonged and made happier by judicious electric treatment. A case of malignant disease of the colon, for instance, was so much benefited by dorso-abdominal faradisation as to make the friends wonder if, after all, there had not been an error of diagnosis.

I have spoken of peripheral neuritis when referring to headache, and this is frequently the condition when headache is complained of. There is a tenderness on pressure on one or both temples, and possibly posteriorly also. Here general electric treatment is, I find, of only small avail; but the vacuum electrode, rubbed over the tender parts till a distinct redness results and remains as a burning soreness for an hour or two, will frequently relieve and finally remove the painful condition. Failing this, cocaine ionisation may act like magic. I usually, when the neuritis is over a well-padded region, such as the back or the shoulder, employ the condenser electrode and finish off with the electric vibrator. I suspect that one reason for failure in cases of so-called rheumatic neuritis of the trunk is that the spinal root of the nerve supplying the part is untreated; for, if careful examination be made of the spine, a tender spot will be felt on the affected side, treatment of which as above will go far towards effecting a cure of the pained part. Massage with the condenser electrode will sometimes remove a chronic sciatica when milder electric measures fail. In very chronic cases the massage must be deep and the applications strong. Excellent results may be obtained by fairly vigorous effluve from the high-frequency solenoid applied over the whole of the spine, strong enough to be just short of sparking and for a period of 15 minutes, for pains in the lower limbs and for a very troublesome condition, nocturnal fidgets, which sometimes render sleep impossible.

Even in organic affections of the spinal cord much good may sometimes be effected by electric applications to the spine. I have known a case of spastic paraplegia with exaggerated knee reflexes and marked ankle clonus arrested, although a year of active medicinal treatment and a prolonged holiday had failed, the case continuing to go from bad to worse. The reflexes are now almost normal and the ankle clonus has practically disappeared, whilst the patient is at least as well now as when the disease was first detected. The only electric treatment in this case was 15 minutes' daily application of the effluve to the whole of the spine. Another case, in a woman where the paraplegia had lasted for nine years, has remained well during the past ten years. No one could now suspect that she had ever been paralysed. In this case the treatment was by faradisation between the upper dorsal region and the feet once or twice a week for five months.

The history of auto-condensation since its introduction has been a varied one. I feel sure, from what I hear and read, that it is losing, if it has not already lost, its reputation; and yet no form of treatment is at present giving me more satisfaction. Why is this? I attribute my increasing success in part to my practice of giving smaller doses than formerly, and to the habit of controlling the environment of the patient on the days of administration of the treatment, as well as to the care with which I select my cases.

A common reason for failure in cases which are otherwise doing well is that patients do not allow sufficient time for repose, or at least cessation from strenuous work, before and after each application. The business of having the applications is hurried through. They come for the treatment fatigued perhaps, and they arrange for some important duties as soon as they leave—a dressmaker to see, some shopping to do, or a call to be made. This is fatal. An hour or two of quiet rest, not necessarily of idleness, before each application and the same after it will make an immense difference in the result, unless when merely local conditions are being treated, and often even in such circumstances if the best results are to be obtained. In cases of severe neurasthenia indeed I insist upon absolute rest for an hour or two before and after each application, permitting perfect freedom of action during the rest of the day.

Regarding the question of regulation of dose I usually begin with one of 200 milliampères only. In one or two cases I have started the treatment with a milliampèrage of 100 only, especially where the blood pressure was low and the patient liable to fainting turns. At each after-visit the effect of the previous sitting is ascertained. If exhaustion has followed it a smaller dose is given. If a sense of increased vitality or a comfortable weariness only is reported the original dose is given or a slightly increased one. If upon inquiry the patient reports a busy forenoon, or an expected active time after leaving, less current is administered than was formerly given.

When the treatment is applied daily therefore the time devoted to it is considerable, though the actual application is only of 15 minutes' duration. Where three applications a week are given I permit absolute freedom of action on the alternate days with reasonable avoidance of fatigue. All this may seem trifling and not worth mentioning, but it must not be forgotten that great results are only obtained by attention to trifles; and I have had such good results from auto-condensation when all else, including a prolonged holiday, has failed, that I am inclined to continue my practice. Let me here say that any holiday which can be obtained will be much more pleasant and more profitable after such treatment than before it.

Before leaving the subject of high frequency I should like to draw attention to the beneficial action of local applications, as distinguished from auto-condensation, in gastro-intestinal trouble. For example, the effluve over the abdomen for five or ten minutes before the application of auto-condensation will aid materially. So also will the same applied over the spine behind the arch of the aorta assist in cases of cardiac dilatation. In cases of eczema, when the health has improved and general irritability has been relieved by the auto-condensation, the local condition may remain practically uninfluenced till the vacuum electrode has been applied to the parts in sufficient strength to cause a sense of surface burning, when pruritus will cease and the previous rough red surface will disappear, but usually I find on the parts treated only. I wonder if any of you have observed how nervous a patient may become after about ten minutes of auto-condensation if placed on the couch shortly after a full meal. The best results, I find, are to be obtained shortly before a meal. I suspect that treatment is often withheld because the patient, usually a woman, is terrified of it. I never allow this to influence me where everything else has failed. The dread disappears, the patient's countenance changes, and a previously hopeless invalid is delighted to find herself well again.

I have absolutely failed in the treatment of diabetes and of confirmed obesity with high-frequency currents—failed, that is, in influencing the specific condition. At the same time, if obese people or diabetics are otherwise ill much benefit may be derived from auto-condensation properly applied. In simple glycosuria, on the other hand, the glucose can be made to disappear early in the treatment of the case, especially where it has been observed to come and go according to the condition of health of the patient. Again, in cases of generalised chronic rheumatic arthritis where there is obviously evidence of profound constitutional disturbance of long standing the results have been unsatisfactory. This is what might be expected. In these cases I have tried both high-frequency and ionic medication. If the case is made worse early in the treatment I am more hopeful, though it is difficult to get the patient to see it in that light. A possible reason for non-success may be that the length of the treatment should probably be proportioned to the duration of the disease, and this may prove too irksome to the patient. On the other hand, even a relatively short course of treatment may in time prove beneficial, but as the patient may in the meantime have been lost sight of it may be difficult to obtain knowledge of the final result. A case illustrating this came under my care some years ago. The lady had suffered for 20 years from progressive rheumatoid arthritis, her hands being practically useless. The report at the end of 12 applications of high frequency, local and general, was: "More freedom of movements of arms, but condition of hands and knees unchanged." Three months later the report sent to me was: "Ever so much better, stronger, less pain in joints, and less stiffness." About a year after she called to express her gratitude for the great improvement she then felt. Possibly, therefore, the failure in these cases is less real than at first might appear.

I have heard it said more than once that there are some patients whom electrical treatment in any form disagrees with. I am not prepared to accept such a statement without further details. In such cases I would be inclined to say, Why? when a possible explanation might be forthcoming. This reminds me of the case of a medical friend in the country. He had known of my success in cases of insomnia

when treated by faradisation of the head, and so he had it tried in his own case. The result was such as to make him vow that he would not attempt it a second time. Continuing, however, to suffer, and being so restless from nervous exhaustion that he could not remain at rest in bed, he sent for me in the hope that there might be something in what I had said after all. I took with me an excellent large sliding coil which I had had from Mr. Dean of London, and the current was no sooner applied to the head than the restless movements ceased, and he exclaimed, "Oh! how delightfully soothing." Evidently the first application had been from a small coil, giving therefore a coarse current; for it is not simply the quantity of faradic current but its quality which tells in such cases. Two milliampères can be borne with comfort from such a coil as Dean's, whereas less than one milliampère from an ordinary coil might irritate instead of soothe.

In cases of severe gastric dilatation my experience is that where there is no pyloric obstruction, congenital or acquired, success from electro-therapy may be looked for. Several cases treated by me had a successful result. I shall briefly relate one which came under my care in 1904. The lad had been off work for a year and the stomach had been washed out twice daily for weeks, but this lavage had to be given up on account of pain. Vomiting of sour and frothy material had occurred almost every day. His general condition was such that I decided to try electric treatment for one month only, when if no real improvement resulted he must have gastro-enterostomy performed. I gave him oro-epigastric applications of bi-polar treatment from the high-frequency solenoid, with a spark-gap of 1 mm. in series, which caused rhythmic muscular twitchings extending from the neck to the epigastrium. In a few weeks there was marked improvement. One year later the report given to me was: "Has been working for some months, can eat anything, is stout, and only knows he has a stomach if he gets cold." This is the only form of current which has been successful in my hands in gastric dilatation. One drawback to it is that there is some uncertainty as to the regularity and strength of the muscular movements. Possibly the static-induced current might be as efficient. It could be absolutely relied upon at any rate for regularity and force.

I am sorry to have to report numerous failures in cases of melancholia. Where, however, this is slight and has a definite cause in the patient's mind, especially if it is due to worry and brain fatigue and is accompanied with sleeplessness and general ill-health, and where the asthenia is cerebral more than psychic, success is almost certain. If, on the other hand, the melancholia is irrational, and especially if it is associated with delusions, failure is in my experience just as certain. The removal in such cases of the insomnia seems to have little, if any, influence on the melancholia; and this is notably so where the mental affection has resulted from the loss of a dearly loved husband or wife. In one such instance my advice to the widower to take a new partner in life resulted in a complete cure.

In cases of occupation neuritis I find it safer, if the occupation cannot be temporarily suspended, to give a guarded opinion as to the results of electro-therapy. This is only what might be expected since the cause remains in continued operation. Here I would warn against encouragement at the beginning of treatment of the expectations of nervous optimistic patients, where there may be even justifiable reasons for expecting success. Some necessary patience must be inculcated in these cases, and not too much promised at the start, otherwise possible success may become actual failure through early disappointment.

I have so recently given my experience of electro-therapy as applied to gynæcology that I shall be brief in my reference to this department. I should like to give a warning, however, regarding intra-uterine ionic, or ordinary pelvic galvanic, treatment in cases of disease of one or both ovaries. If the treatment is employed in such cases pain on the part of the patient should be considered as an indication either that too large a current is being employed or that the treatment is in that case unsuitable. I have had cause to regret applying it in such circumstances. In one case I had reason to suspect that intra-uterine high-frequency treatment was the cause of an acute attack of pelvic cellulitis. Since the mere passing of a uterine sound has been known to have such a result, the electric current may not have been accountable in this case; it is difficult indeed to see how it could have been so. I mention the case, however, as a warning.

I have spoken in the early part of my remarks on the importance of correct diagnosis as an aid to success in electro-therapy. Now, I know of no condition more liable to be overlooked, in the case of woman suffering from psychic neurasthenia, than unsuspected, often apparently unimportant if detected, irritable conditions of the vulva. In one case a young woman had been under my care, with only limited success, until I discovered that her mind had for years been unduly concentrated on an irritable condition of the vulva; and it was only when this had received attention that real improvement set in. In another the patient had repeatedly complained of distressing pelvic spasms, which she felt certain were largely the cause of her neurotic condition; but she omitted to mention this to me in her history of her illness. The lady doctor under whose care she had previously been had told her that the vulva was perfectly normal and that the sensations she described to her must be imaginary only. On my first examination of this patient I observed that the vaginal orifice was unduly red compared to the rest of the vulva. Under proper electric treatment this redness disappeared and so did the pelvic spasms, the general health becoming greatly improved as a result. In such cases I find a conical vacuum electrode passed into the vagina an almost certain remedy. In the case of a married lady now under my care long-continued treatment had failed to relieve her of a burning sensation in the vulva. On examination I discovered two minute septic ulcers in the groove at the junction of the hymen with the vulva, too trifling apparently in size to be the cause of much distress. She insisted, however, that this was the situation of the burning. These ulcers disappeared about a week after one application of the galvanic cautery. The burning sensation has greatly diminished; but since it has existed for many years its final disappearance cannot be expected immediately after the removal of the cause, seeing that the general health has been impaired from long years of physical distress and mental anxiety, normal conjugal life having been made impossible owing to the pain resulting. Auto-condensation combined with an ordinary tonic is, however, proving sufficient to restore her nerve tone. As a rule, these vulvar conditions can be detected only by examination in the dorsal position, with a full view of the opened vulva.

The employment of electricity as a sole remedy eliminates all other sources of possible success or possible failure, and makes for education in correct electro-therapy. This is of value in the early practice of the art, but, without doubt, once sufficient experience has been gained, the best results will be obtained by utilising to the full all the resources of the healing art—electrical, medicinal, dietetic, physical, psychic; and he is the most successful physician who has his quiver full of such weapons and who, in cases of difficulty, is fertile in resource.

Glasgow.

A CASE OF TROPH-NEUROTIC ANÆMIA; A SEQUEL.

BY T. WILSON PARRY, M.A., M.D. CANTAB.

AN account of the original attack of this case was published in THE LANCET of Nov. 6th, 1909. I now wish to record two relapses of this case of troph-neurotic anæmia which took place: the first, at an interval of about two months, which ended in a brilliant recovery, in which the blood almost touched its normal state, in response to the same treatment (intramuscular injections of an arylarsonate) which the patient underwent on the first occasion; and a second relapse, which followed about three months after the second recovery and which, for certain reasons, was not suspected till the condition of the blood had passed into an irrecoverable "pernicious" type.

To summarise the case briefly. A lady, 54 years of age, underwent a course of intramuscular injections of para-aminophenylarsonate of sodium from June 30th to August 9th, 1909, 100 grains of this arylarsonate being injected. During this period her hæmoglobin mounted from 65 to 93 per cent.; her red corpuscles from 3,500,000 per cubic millimetre to 4,800,000, and her white corpuscles from 2800 per cubic millimetre to 3250. The polymorphic cells were raised from 34 to 55 per cent., while the mononuclears dropped from 32 to 21 per cent., and the lymphocytes from 34 to 24 per cent. The colour index was 0·9 per cent. on both occasions.

A few poikilocytes, megalocytes, microcytes, and chromaphile granules were found at both examinations, but no normoblasts or megaloblasts could be discovered. The patient left for the seaside, with a nurse, on August 19th, and was progressing most satisfactorily in every way when the nurse left her on the following Sept. 2nd.

On Oct. 16th the patient returned home, with a temperature of 102° F., and I was called in to see her on the evening of the 19th, when her temperature was 101·2°. It appears she had been feeling poorly the past two or three weeks, had lost her appetite, and her legs had begun to ache as they had done at the commencement of her previous attack. For the past eight days she had been unable to walk comfortably on this account, and in the nights she had had profuse perspirations. During these latter days also she had retched a great deal, as had happened in her original attack, but vomited for the first time on Oct. 19th. Her conjunctivæ were again colourless, and she felt faint and giddy when she raised her head from the pillow, but this was not as marked as on the previous occasion. Her skin was of a pale lemon tint, but moist. I could not discover a hæmic murmur. Her pulse was 92, but not as soft as might have been expected; the sphygmomanometer gave 110 mm. Hg. I lost no time in commencing treatment, injecting 2 grains of soamin intramuscularly, morning and evening, on Oct. 20th. These doses I repeated both morning and evening on the 22nd and also on the morning of the 24th, but abstained from giving the injection in the evening of that day as vomiting and diarrhœa with abdominal pain set in and she had also certain ocular symptoms—namely, the feeling that her eyes were too big for their sockets, and when she looked at an object part of it was always replaced either by a dark blur or by an image which appeared "red like fire." This made me feel that this series of symptoms might mean a passing arsenical toxæmia. I accordingly waited a day and a half, and then began with half the previous doses, slowly increasing them to a maximum of 5 grains, which was given in two half doses, on alternate days and then gradually lessened till I finished up with 1 grain a day. The whole period for the injection of the full hundred grains covered 52 days, as compared with the 39 days on the previous occasion. Besides these injections I administered 10 grains of salol twice a day, half an hour before lunch and dinner, as an intestinal antiseptic, and the fresh juice expressed from a pound of raw beef-steak every day. The result was excellent, as will be seen in Table I., which shows the two examinations of the patient's blood made by Dr. Wyatt Wingrave, the first one on Oct. 20th, the day on which I began injecting the arylarsonate, and the second on Dec. 11th, the day after I had injected the hundredth grain.

TABLE I.

	Oct. 20th, 1909.	*Dec. 11th, 1909.*
Hæmoglobin	75 per cent.	95 per cent.
Red corpuscles	4,000,000	4,850,000
White ,,	3,500	4,500
Differential:		
(*a*) Red—		
Poikilocytes	A few.	A few.
Megalocytes	None.	—
Microcytes	A few.	A few.
Chromaphile granules	,,	,,
Normoblasts	None.	None.
Megaloblasts	,,	,,
(*b*) White—		
Polymorphic cells	50 per cent.	74 per cent.
Mononuclear ,,	5 ,,	1 ,,
Lymphocytes	45 ,,	25 ,,
Eosinophiles	0·5 ,,	1·05 ,,
Colour index	0·95 ,,	1·05 ,,
Platelets	Slightly below average.	Numerous (above average).
Bacteria	None.	None.

While the blood on Oct. 20th was not in as poor a condition as it was on June 30th, it can be seen at a glance from the above table that the examination on Dec. 11th demonstrated the fact that the arylarsonate injections had wrought wonders by bringing the blood almost up to its normal character, the only abnormalities being a slight deficiency in hæmoglobin and red corpuscles. The white corpuscles were now normal in number and the lymphocytes had now regained their correct ratio. Coincident with this treatment was a most marked clinical improvement. The patient, who was at first too ill to take note of anything, was got up on to a sofa by an open window on Nov. 1st, was taken out in a bath-chair on Nov. 23rd, and was able to take half-an-hour's walk on Dec. 12th. Hyperacusis, which had been present, disappeared by Nov. 15th, but the eye symptoms did not entirely depart till Nov. 22nd.

The patient went to Eastbourne with a nurse on Jan. 27th, 1910, looking exceedingly well, carrying a slight colour in a usually pale face, and her fingers also had a decidedly pink blush. On Feb. 9th the nurse wrote to say: "Mrs. —— is going on very nicely. Her appetite is very good and she is sleeping much better. She was weighed the day before leaving home and had gained 1 lb. 4 oz. in a fortnight. To-day we found she had just doubled that and had gained 2 lb. 8 oz. since we came here, her weight now being 10 st. 2 lb. 8 oz. without her clothes. In spite of this gain Mrs. —— is taking much more exercise, being out nearly three hours in the morning, and when fine going out in a bath-chair one and a half hours in the afternoon." On Feb. 28th I had further news, telling me that the patient "had been weighed on the 23rd and had gained 2 lb. all but 2 oz., so that is 3 lb. in the last fortnight. She gets very depressed at times, and the last few days fears she is becoming more anæmic; she says she has an exhausted feeling at times and feels a shortness of breath, that she does not enjoy her food so well, and feels slightly sick. I do not think her lips and eyelids are quite so red as when she came here, but apart from that she is taking her food well and sleeping better. I have let her go back this week to taking the meat juice three times in the 24 hours and the Levico water twice a day. She also takes a pint of milk and the meat juice between 7 P.M. dinner and 7 A.M. tea, so that she could not possibly take more than that." The nurse went on to say that she wished to call in a local medical practitioner, but unfortunately the patient, whose nerves were not of the strongest at the best of times, absolutely refused to have anyone called in, or even allow the nurse to communicate with me, as she felt she did not wish to consider herself ill enough to need a medical man. The consequence was that valuable time was lost. When at length she permitted the nurse to have medical help Mr. H. D. Farnell, who was summoned, recognised that a relapse was inevitable and communicated with me at once. I requested that a blood examination should be immediately made, and this was accordingly done by Dr. H. S. Gabbett, whose report will be found below in Column 1 of Table II., showing a sudden alarming deterioration in the condition of the blood since the previous examination on Dec. 11th, 1909.

TABLE II.

	March 12th, 1910.	*March 22nd, 1910*
Hæmoglobin	35 per cent.	—
Red corpuscles	1,750,000	1,600,000
White ,,	2,400	Not counted.
Differential.		
(*a*) Red—		
Poikilocytes	Numerous	—
Megalocytes	,,	—
Megaloblasts } Normoblasts }	[Presence of nucleated corpuscles. 10 seen while counting 100 leucocytes, most of them megaloblasts.]	
(*b*) White—		
Polymorphic cells	21 per cent.	25 per cent.
Mononuclear ,, (large)	4 ,,	24 ,,
Lymphocytes	74 ,,	51 ,,
Eosinophiles	1 ,,	—
Platelets	Greatly diminished.	—
Colour index	0·89	—

[If the normal corpuscular count is taken at 5,000,000 the index is 1.]

The result of this examination was most alarming, and one was painfully aware of the fact that it was more than probable that the patient had passed the line from which recovery was possible, as the state of "pernicious anæmia" was now undeniable. The suddenness of this deterioration was all the more amazing considering the degree of excellence the blood had attained on Dec. 11th, when its normal character was within an ace of being reached, and the short time (say about Feb. 20th) that any symptoms indicating a relapse had manifested themselves.

The patient arrived home on March 17th in a greatly

exhausted condition. Two grains of soamin were immediately injected on arrival, salol was administered by the mouth, and oxygen was given freely at intervals. The juice from a pound of raw beef was also given every 24 hours. Thinking that the double return of the hæmolysis might be caused by an intestinal toxæmia of microbic or chemical origin, I asked Sir Almroth Wright to see the case with me. He kindly met me in consultation on March 19th, and was of opinion that such was most probably the case and suggested that the fæces should be examined, the microbes isolated, and each one tested (1) against the patient's blood as to comparative powers of resistance against each of the different microbes discovered; and (2) against a normal "pool" of healthy men's blood. Sir Almroth Wright made an examination of the patient's blood (Table II., Column 2) which showed further deterioration in the red corpuscles in the space of a week. His report was: "Mrs. ——'s red blood corpuscles measured 1½ volumes in 10, instead of 5 volumes in 10. I found also a considerable number of macrocytes which point to a profound disorganisation of the blood-forming apparatus." Referring to the differential count of white blood corpuscles Sir Almroth Wright continues: "These are practically the same as Dr. Gabbett's figures, for the line one draws between large mononuclears and lymphocytes is often an extremely arbitrary line. There was a great reduction in the white blood corpuscles, but I did not count them. The blood picture is, as you see, almost as bad as it could be, and the prognosis is correspondingly bad." He suggested the administration of 15 grains of thymus tablets three times a day to increase the number of white blood corpuscles. The examination of the fæces was kindly done for me by Captain J. Matthews, R.A.M.C., whose report is as follows:—

I found five microbes on lactose bile-salt plates and in sugars they gave—

	Lactose.	Glucose.	Mannite.	Dulcite.	Cane sugar.
No. I.	+	+	+	+	−
,, II.	+	+	+	−	−
,, III.	+	+	+	+	+
,, IV.	+	+	+	+	*+
,, V.	+	+	+	+	−

* Slight gas only.

This makes—

Nos. I. and V. = Bacillus coli communis.
,, III. ,, IV. = Bacillus Friedländer.
No. II. = Bacillus acidi lactici of Hueppe.

The indices were:—

No. I.	0·71	No. IV.	0·79
,, II.	0·46	,, V.	0·90
,, III.	0·76		

I also plated on plain agar to see if there were any undue quantity of streptococci. There were, curiously enough, none, so I do not think streptococcus vaccine is indicated, and if we gave it we should not know what strain to give.

Captain Matthews prepared a vaccine from a culture of the B. acidi lactici of Hueppe, and I injected 2,500,000 at 10 P.M. on March 24th. The specimens of the blood sent Captain Matthews after this injection showed no change. On the evening of March 26th I injected 5,000,000, but it was all of no avail, as the patient sank rapidly, and passed away on the evening of March 30th.

Remarks.—There has been much talk of late concerning the arylarsonates. While one school affirm them to be of inestimable value, another, which has perchance not watched the effects of the drug carefully enough when slight indications presented themselves, so as to make them either reduce the dosage they were giving or to stop the drug entirely for a time, denounces these arylarsonates with a vigour that might give one the impression, had one had no experience with them, that they were both useless and dangerous and should never be employed. This case has taught me one thing, that had it not been for the arylarsonate I used, my patient would have rapidly sunk into a state of irrecoverable pernicious anæmia eight or nine months previously. Though the drug was not curative it was ameliorative, and the happy time spent by the patient each occasion the drug temporarily relieved her deplorable condition only proves to me how great is its true value. We unfortunately at present understand very little about the causes of these obscure anæmias. Had we been able to discover a cause and deal with it effectively it is quite possible that no relapse would have taken place. The picking up of the patient from an anæmic cachexia by the use of intramuscular injections of an arylarsonate I believe to be due to the splendid temporary tonic effect of this drug upon the blood-forming apparatus, possibly through the intervention of the nervous system. It must not be forgotten that nervous shock appeared to be the cause of this anæmia at the outset. I know no other drug that could have taken its place, producing the same result in the same time; so that even if by its use life cannot be saved but can be happily prolonged, that drug surely is of priceless value when used in suitable cases and when handled in a proper manner.

Crouch End Hill, N.

Reviews and Notices of Books.

Human Physiology. By Professor LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome. Translated by FRANCES A. WELBY, and edited by Dr. M. CAMIS, Institute of Physiology, University of Pisa. With a Preface by J. N. LANGLEY, F.R.S., Professor of Physiology in the University of Cambridge. In four volumes. Vol. I.: Circulation and Respiration. With 263 illustrations. London: Macmillan and Co., Limited. 1911. Pp. 592. Price 18*s.* net.

AFTER a short introduction on general physiology and such themes as materialism, neo-vitalism, energetic and psychical monism, pragmatic pluralism, and the general physiology of the cell, the author devotes three chapters, or about 80 pages, to living matter, its chemical and physical basis, its fundamental properties, and the conditions by which it is determined, in this way giving an all-round view of the general physiology of plants and animals. About 60 pages are devoted to the blood, including its formed constituents and blood plasma. In this chapter Cornstein must, we think, be intended for Cohnstein. A method of estimating fibrin-ferment, viz., that of Carbone, is not usually to be found in English text-books. The chapters on blood are very readable, comprehensive, and concise.

One chapter is practically devoted to the discovery of the circulation of the blood. Professor Langley, who has written a preface to the English translation, says: "It will be a shock to many English readers to find that Professor Luciani allots the discovery of the systemic circulation of the blood to his countryman, Cesalpinus"; while he is good enough to say that Harvey's little book of 72 pages is "unmistakably the masterpiece of a man of genius." It should be no shock; the pretence has often been made. That Harvey had forerunners who understood part of the story no one doubts. But Harvey's claim is justified over and over again, and will continue to be accepted.

The chapter on the mechanics of the heart and all that relates to cardiac physiology is one that Professor Luciani is peculiarly fitted to write, for under the guidance of Ludwig he began his classical researches on the beat of the excised heart. It would have been better if the translator had avoided Riolan's phrase, "peri-systole," as used by the author to indicate what we know as the pause—i.e., the resting period of the heart as a whole. The simplicity of the cardiac cycle is further complicated by the introduction of "pre-systole." We are at one with the author that it was Ceradini and not Krehl who introduced the present view regarding the opening and closing of the semilunar valves. Professor Luciani about 40 years ago revived the theory of "diastolic activity" of the heart, and he rejoices to think that Stefani has placed this theory on a firm experimental basis. The reader will find the matter fully set forth in the text. While certain parts of this chapter are very fully elaborated, the important question of the work of the heart is dealt with less fully than in most English text-books. About 50 pages are devoted to the blood stream, of which a concise summary

is given. The well-known apparatus of Marey for demonstrating the effect of intermittent flow of fluid through a rigid and an elastic tube is attributed to Mosso (Fig. 90), although its source is correctly stated in the text. For English readers it might have been well to introduce other forms of sphygmomanometers in addition to those mentioned in the text, and the same might be said of the sphygmograph, which the author asserts has proved "to be of very little diagnostic value." The figure of the plethysmograph of François-Franck (Fig. 115) should be replaced by a more modern form. Sixty pages are given to cardiac muscle and nerves, a subject that the author has largely made his own, and he treats it with a wealth of detail, entering fully into the history and evolution of the nature of the cardiac beat, and discusses in the light of Carlson's experiments on the heart of the king-crab (Limulus) the relative merits of the myogenic and neurogenic theories of the heart-beat. A similar question arises and is discussed in connexion with the *a.v.* bundle. About 30 pages devoted to the vascular muscles and nerves complete the story of the circulation.

The chemistry and physics of respiratory exchanges are clearly and explicitly set forth, including an excellent historical account of this subject. Full justice is done to the work of John Mayow (1640–79) and also to the grand contributions of Spallanzani (1729–99), so important in relation to "internal respiration." A description or figure of a simpler form of gas-pump than that of Pflüger would have been useful. Oxidases are mentioned in the introduction, but we did not find a reference to them in relation to nternal respiration. Under Mechanics of Respiration we failed to find any reference to the recent work of Keith. Sixty pages are devoted to the Nervous Control of Respiratory Rhythm, of which subject a very elaborate and well-illustrated account is given. Fifty pages are given to Lymph and the Interchanges between Blood and the Tissues. There is added in this chapter an account of the Ductless Glands. The indexes of subjects and of the authors cited are good, and to each chapter is added the modern literature of the subject with Recent English Literature collated by Dr. Camis of Pisa. The illustrations are good and well produced.

We offer a hearty welcome to the work of the veteran professor of physiology in Rome, one of the early Italian pupils of Ludwig and the successor of Moleschott. Few men have such an all-round knowledge of physiology as Luigi Luciani or so wide an outlook on physiological problems, both in their modern and in their historical aspects. Moreover, this treatise will introduce to English readers much of the work done by his compatriots, which is none too well known in either England or America. It is rather remarkable that the translation into English of such an all-round comprehensive work should have been so long delayed. All the more, therefore, do we congratulate Miss Welby on the successful manner in which she has performed her work. We wish this and the succeeding volumes every success in their English garb, and we hope that the other three volumes will soon make their appearance.

The Principles and Practice of Modern Otology. By J. F. BARNHILL, M.D., Professor of Otology, Indiana University, &c., and ERNEST DE W. WALES, B.S., M.D., Clinical Professor of Medicine in Indiana University, &c. With 314 original illustrations, many in colour. Second edition. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 598. Price 24*s.* net.

THE opening chapters of the book are devoted to the anatomy and physiology of the temporal bone and auditory apparatus. The third treats of the bacteriology of the ear, and in dealing with this matter a few important points may be worth referring to, especially the differences between the course of otites according to their exciting organisms. Though the pneumococcus is the more rapid in action, it shows a greater inclination to extension than the streptococcus, and at the same time it more often remains latent for a considerable period. The authors sum up their conclusions under 12 headings, which may be read with considerable advantage. The Causation of Ear Disease forms the title of the following chapter, and the next four chapters are devoted to diseases of the external ear. The principal point worthy of notice is the very full description given to its cutaneous disorders. The subsequent eight chapters are devoted to diseases of the external meatus.

Chapter XVII. deals with the methods of examination of the patient, and includes amongst its illustrations the photograph of a room fitted up for that purpose, and in Chapter XVIII. the authors give a very full report of the so-called universal acoumetric formula adopted at the Eighth Otological Congress at Budapest. The nineteenth chapter deals with the influence of nasal and naso-pharyngeal conditions upon the ear, while Chapters XX. to XXIII., inclusive, treat of acute conditions of the middle ear, preceding a chapter on acute mastoiditis and one describing the operations necessary for the treatment of acute suppurative conditions of the mastoid. Five chapters are devoted to chronic purulent otitis media, giving its effects on the mastoid bone and the operations necessary for the relief and cure of chronic suppurative conditions involving the middle ear and mastoid; the next eight chapters deal with the intracranial complications, and the following three with chronic non-suppurative otitis media. The remaining portion of the book is devoted to diseases of the perceptive portion of the hearing apparatus.

This is by far the best American work on otology that has been published for some time, and in their second edition the authors have been able to improve the text materially by the addition of much interesting and essential matter. We recommend this book with all confidence to those interested in otology.

Micro-organisms and Fermentation. By ALFRED JÖRGENSEN, Director of the Laboratory for the Physiology and Technology of Fermentation, Copenhagen. Translated by S. H. DAVIES, M.Sc. Fourth edition, completely revised. London: Charles Griffin and Co. 1911. Pp. 489. Price 15*s.* net.

THERE are probably few who are so well able to deal with the subject of micro-organisms considered in relation to fermentation as the author of this book. He has been associated with the fundamental work of Hansen in the application of micro-biological methods to the brewing industry, and he has himself enriched our knowledge of this and kindred industries by numerous researches of great practical and scientific interest. He has, in addition, been for many years the director of a technical laboratory in which large numbers of students have been trained. As might be expected, therefore, the book bears the impress of first-hand information, and has the interest which attaches to the record of original work. Even the historical portions of the subject gain an air of greater reality when dealt with by an actual worker in the field of research. The book has reached its fourth edition. It was first published in 1886, and has grown to its present size in the attempt to incorporate the numerous researches on the science of fermentation which have appeared since that date. This gradual growth is perhaps responsible for some slight confusion in the arrangement of the subject. For the book must not be considered merely as a technical handbook of the fermentation industries; it takes a wider view than this, though undoubtedly the micro-organisms, their

characters and modifications, are always seen from the standpoint of fermentation activity.

Opening with a review of the methods for the microscopical examination and cultivation of micro-organisms, the author passes on to consider the biological examination of air and water. In this part the work differs from the usual medical bacteriology in that the zymogenic properties are more important than the pathogenic, so that, for instance, in dealing with disinfection various antiseptics are regarded in the light of their suitability for the brewery rather than for the hospital. In the chapter on bacteria, which follows, it is the fermenting organisms with which the work is chiefly concerned, and bacteria are grouped according to their chemical action as lactic acid, acetic acid, and alcohol-forming bacteria without regard to morphology. Those causing beer and wine diseases are naturally regarded as important. The moulds are similarly treated.

As might be expected, about half the book is concerned with the yeasts. Probably to the general reader the most interesting part of the treatise is that which deals with the theories of fermentation and the very full account given of the yeast enzymes. Of more restricted and technical interest is the discussion of the morphology and physiology of various yeasts, but here also there are numerous interesting biological problems dealt with, such as the occurrence of variation, the causes producing it, and the stability of the varieties found. A description of a large number of yeasts is given, and the book ends with a chapter on the industrial application of pure yeast culture. A very full bibliography is furnished, and there is a good index.

The book is of good appearance and is well and accurately printed. It is an indispensable text-book for all who have to deal with the fermentation industries, and is of interest to all bacteriologists.

The Chemistry of Food and Nutrition. By HENRY C. SHERMAN, Ph.D., Professor in Columbia University. New York: The Macmillan Company. 1911. Pp. 357. Price 6*s.* 6*d.* net.

IN this work food is chiefly considered in its nutritive relations, while the detailed description of individual foods and the chemical and legal control of the food industry, we are told, may be treated in a future companion volume. The principles of the chemistry of food and nutrition with special reference to the food requirements of man are set out in the following order. First, the organic foodstuffs are dealt with, carbohydrates, fats, and proteins, much on the usual lines. Next follows an account of the general composition of foods (a very short one) and of the action of ferments, in which the author cites the well-known classification of enzymes, as given by Howell in his text-book. The description of the course of food through the digestive tract occupies about thirty pages. In dealing with the stomach "hormone" or "gastrin"—though this word is not mentioned—the author omits the name of Edkins. The X ray experiments of Cannon are largely drawn on, but there is no reference to the work of Hertz. The account of "the fate of the foodstuffs in metabolism" is excellent as well as suggestive. When dealing with the fuel value of food the work of Atwater is fully presented. Instead of using Rubner's heat-value results obtained on dogs—i.e., for carbohydrates 4·1, fats 9·3, and proteins 4·1 calories—the author uses for carbohydrates 4·1, fats 9·45, and proteins 4·35 calories per gramme as more accurate for man.

There is an interesting chapter on the conditions affecting the total food requirement. Protein metabolism is next fully discussed, and many experiments are quoted from standard authors, and in discussing Chittenden's results the author says "that to maintain nitrogen equilibrium with the full store of protein which is carried on an ordinary diet must necessarily call for a somewhat larger amount of protein than was used in Chittenden's experiments, probably in the neighbourhood of 75 grams of protein per man per day." Food habits and dietary standards are next discussed. Somewhat on the lines adopted by Bunge, nearly 30 pages are devoted to iron in the food and its functions of nutrition, and a similar account is given of inorganic foodstuffs and mineral metabolism—a subject all too frequently forgotten in text-books. A short chapter on Value and Economy of Foods—the prices being given in dollars—ends the text. An appendix of over 20 pages is filled with elaborate composition tables relating to foods.

The book is thoroughly readable, the subject-matter is dealt with in a clear, precise, and easily understood form, and seems to us to embody a trustworthy and not too lengthy account of the great principles of the chemistry of food and nutrition. At the end of each chapter a list of books of reference is given. There are a few misprints: for instance, on p. 95 Chauveau appears as Chaveau.

Vorlesungen über Infektion und Immunität. (*Lectures on Infection and Immunity.*) Von Dr. PAUL TH. MÜLLER, a.o. Professor der Hygiene an der Universität Graz. With 21 figures in the text. Third enlarged edition. Jena: Gustav Fischer. Pp. 451. Price, paper, 7 marks; bound, 8 marks.

THE additions constantly being made to our knowledge of the mechanisms of infection and immunity, as well as the complexity of much of the experimental work upon these subjects, render it a matter of considerable difficulty for anyone except an expert bacteriologist to keep abreast of the literature. A book presenting in readable and philosophical manner a review of the main facts concerning these matters, considered from the theoretical as well as from the practical standpoint, should therefore be of undoubted value. In the volume of lectures before us Professor Müller supplies such a book. The nature of infection and of the bodily responses is considered systematically, and the practical applications of the information obtained in relation to these problems are clearly stated. Sufficient details in regard to important experimental work are given to render it intelligible. Facts are clearly differentiated from theoretical considerations, and the discussion of any question that is still the subject of controversy is always critical and dispassionate. The arrangement of the material is also worthy of commendation. Each chapter deals fully with some special aspect of the problems of infection and immunity; authorities are quoted in the text; and in addition a bibliography of each special subject concerned is given.

After a brief introductory chapter the channels of infection are considered, then the nature of bacterial poisons and their distribution and localisation in the body are discussed. Questions of incubation and virulence and of the behaviour of the organisms in the infected areas are next dealt with. The nature and scope of phagocytosis and of the bactericidal and hæmolytic properties of the body fluids are analysed in considerable detail. An interesting chapter is devoted to a discussion of the nature and uses of the opsonins. The views of Sir Almroth Wright are clearly epitomised and critically examined. Professor Müller lays stress upon the difficulties of controlling inoculation by opsonic index determinations, and while admitting that Wright's method gives good results points out that these do not necessarily establish the correctness of his theory of immunity.

Several chapters are devoted to a full examination of active immunisation and the processes underlying it, in so

far as they are at present known. The nature of the various antibodies, the question of their specificity, their relation to variations of temperature, and their seats of origin are all discussed, and the evidence in regard to these problems is simply presented. The nature of the combination between antigens and their corresponding antibodies is next dealt with, and the quantitative relations of these combinations are discussed. A separate chapter is given to a consideration of Ehrlich's researches upon toxins and antitoxins, and the theoretical speculations of both Ehrlich and Arrhenius to explain the facts observed, are critically examined. Professor Müller quotes some observations of his own in this connexion, which he regards as being opposed to the views of Arrhenius. The characters of lysins, such as hæmolysins, bacteriolysins, and cytolysins, and of their corresponding antilysins, are next considered. The nature and mode of action of complement, the relations between it and the immune body, the characters of the receptors and of various antibodies, such as antilysins, anti-amboceptors, anti-complements, and complementoids, are reviewed and illustrated by references to the well-known diagrams of Ehrlich and Morgenroth. Agglutinins and precipitins are considered in similar detail, and then Ehrlich's side-chain theory and recent variants of it are presented and discussed.

The practical applications of the general principles studied are set forth in detail, together with statistical and other reports as to their value. The forms of antitoxic and antibacterial immunity are defined and differentiated, and the general principles underlying the cure and arrest of infective diseases are fully and clearly enunciated. Special chapters are devoted to anaphylaxis and to the practical results of protective inoculation and serum-therapy. The application of immunity reactions to purposes of diagnosis is discussed at considerable length, and all recent methods are included. Professor Müller's book is one we can thoroughly recommend for supplying in a form convenient for reference a general exposition of all the aspects of immunity and infection.

LIBRARY TABLE.

Outlines of Psychiatry. By WILLIAM A. WHITE, M.D., Superintendent, Government Hospital for the Insane, Washington, D.C. Third edition, revised and enlarged. New York: The Journal of Nervous and Mental Disease Publishing Company. 1911. Pp. 272. Price $2.50.—The student will find in this third edition of Professor White's Psychiatry a compendium of mental disease written from an essentially modernist standpoint. It is thoroughly readable and therefore enjoyable; the author's style is graced with picturesque expressions and at the same time pleasantly free from Americanisms. Chapter VII., on the Principles and Methods of Examination, occupies some 40 pages, and is altogether admirable from the standpoint both of theory and of practice. The adoption of the methods employed by the author cannot fail to be profitable. Mental disorders at best are often obscure enough, and no pains should be spared to throw light from any quarter on their phenomena, hence the necessity of a comprehensive scheme of examination. The book has been written especially for the student, and its excellent qualities will, we feel sure, be appreciated by him.

Science and the Criminal. By C. AINSWORTH MITCHELL. London: Sir Isaac Pitman and Son. 1911. Pp. 240. Price 6*s.*—In this volume some account is given of the manner in which certain scientific discoveries have been utilised to assist the cause of justice. The book is written in a popular manner, and is not in any way intended as a treatise on medical jurisprudence. The principles upon which scientific evidence is based are briefly described, and numerous illustrative cases add interest to the work. The systems of personal identification are discussed, and the uses of photography, anthropometry, and finger-prints are indicated. Numerous trials for poisoning are mentioned, and short accounts are given of the most notable. The identification of human blood and its differentiation from that of animals are described at some length, the precipitin test receiving due notice. The selection of the cases and the manner in which the whole book is written show good judgment, and all unnecessary sensationalism is carefully avoided.

Aids to Memory for First-Aid Students. By L. M. FRANK CHRISTIAN, M.B., C.M. Edin. Fourth edition. Additionally illustrated. London: St. John Ambulance Association. Stockport: Connell and Bailey. Pp. 48. Price 6*d.* net.—One of the best ways of memorising the contents of a book is to make a summary of the information contained in it, and the little book under notice is really a summarised arrangement of first-aid teaching, which can be used either in connexion with a recognised text-book or for class instruction. The notes are arranged under different headings in such a way that the student can easily find a methodical summary of instructions and rules relating to any division of his subject, and both those who have already undergone a course of training and those who are commencing the study of first aid will find the book a practical help; in the one case as a means of refreshing the memory, and in the other as a means of tabulating their knowledge. The illustrations depict actual conditions under which accidents happen. The pictures showing two supposed cases of rescue from contact with live wires are particularly noteworthy, as accidents from this cause are likely to increase with the more general use of electricity, and so far but little attention is paid to this subject in first-aid books.

Recollections of an Irish Doctor. By LOMBE ATTHILL, M.D. Dub. London: The Religious Tract Society. 1911. Pp. 238. Price 2*s.* 6*d.* net.—This is a pleasant, chatty collection of—as Dr. Atthill confesses in his preface—quite unimportant reminiscences. To use his own words, the book "merely narrates incidents in the ordinary life of an ordinary man," but the recollections of one who has lived under five monarchs—namely, George IV., William IV., Victoria, Edward VII., and George V.—are well worth reading by anyone who has not himself reached a great age, for they describe a mode of existence as remote from the present as the days of Elizabeth. Dr. Atthill's descriptions of his early life at home and at school, both in England and in Ireland, are extremely interesting, and although he did not have such thrilling experiences at his Irish school as those described by Trench in his "Realities of Irish Life," yet his account of the sanitary arrangements would cause a modern board of education to hold up its many hands in horror. This was about 1841; and lest we should be suspected of comparing Ireland unfavourably with England we hasten to add that at a much later date neither Winchester nor Eton was conspicuous for either good feeding or proper sanitary conditions. Dr. Atthill's account of the Dublin canal boats are by no means so favourable as those of Mrs. Major O'Dowd, as detailed in "Vanity Fair," but they were evidently a less uncomfortable mode of travelling than the coach, although extremely slow. The value of the book lies in the fact that it gives a modest picture of the life of a man who succeeded in his profession, brought healing and hope to thousands of sufferers, was an honest and true friend, and one who at the beginning of his career had a very uphill battle to fight against adverse circumstances. Apart from his own reminiscences, Dr. Atthill gives us a most interesting account of the foundation of the Rotunda Hospital, of which establishment he became Master in 1875, and into the management and organisation of which he introduced many valuable improvements.

Marriage and Parenthood: The Catholic Ideal. By the Rev. THOMAS J. GERRARD. New York: Joseph F. Wagner. 1911. Pp. 179.—This book—which we must assume is a fair representation of the Roman Catholic viewpoint on the subjects treated, since it bears the imprimatur of the Archbishop of New York—aims to promote and foster those ideals of the home life, the marital relationship, and the responsibility of parenthood, which other Christian communities also consider desirable, but for which the former upholds the indissoluble sacramental idea as the only effective basis. The author, while considering that reticence in regard to the most intimate, the most delicate, and the most sacred marriage relationships is a strong protection against temptation, yet admits that there is some knowledge of sexual subjects that all should have. His chief difficulty has been to decide what must be left out, and he says that what has been retained has been retained by advice of authority. In the practical part of the work it is to be noticed that great attention is paid to the teachings of science, particularly medical science, in such subjects as the choice of a mate, the question of conjugal restraint, the care of the pregnant and parturient woman, and particularly in the chapter on sexual instruction for the young. The time to keep silence and the time to speak is well denoted in the following words: "Knowledge should never be thrust into the child's mind before it is asked for. The state of innocence or ignorance, whichever we like to call it, is better kept untouched as long as possible. To put sexual images into a child's mind before due time is to start a tendency towards precocity and moral depravity. ..... There comes at length a time when the story of the stork and the doctor fails to satisfy. The dawn of a more intelligent interest begins to glimmer. It comes so innocently, so naïvely, that it is just as likely to express itself in the presence of the mother as in the presence of other and older children. That is the mother's opportunity. Then, and not until then, may she give the information."

The author points out that the knowledge sought for is primarily what is meant by being born, rather than how children are begotten. Difficult as the latter subject is, however, if the parents do not speak in due course children will get their first knowledge from undesirable sources and in an undesirable manner. But here, again, more restraint is to be observed than some at the present day are advocating. "There is no need whatever for a full and particular description of the sexual act. Much less is there need of diagrams and pictures of the human body." The lower forms of life are best to start instruction from, but the manner of giving information is more important than the matter. We are decidedly of opinion that the following statement by the author on one moot point puts the essential truth of the matter in a nutshell: "A proposal has been made, and in European countries partly put into practice, to enlighten young minds concerning the many extreme forms of sexual perversion. This instruction I hold to be decidedly pernicious. If the boy is warned against the more common sins he will at once recognise the less common and more heinous ones, if the temptation should arise." We also agree with the author that books dealing with the extreme forms of sexual perversion should not be read even by adults, unless their profession obliges them to deal with such cases.

Faith, Medicine, and the Mind. By CHARLES REINHARDT, M.D. London: The London Publicity Co., Limited. 1911. Pp. 231. Price 5*s.* net.—Readers of that clever collection of stories entitled "In a Glass Darkly" will remember Mr. Lefanu's character, Dr. Hesselius, and his disquisitions upon the inner eye and the methods by which this inner eye may be opened or shut. Dr. Reinhardt, in the book before us, formulates a theory much of the same kind in his explanation of faith healing, telepathy, hypnotism, and similar phenomena. His "psychic sphincter" and "diffused mind" are designed to give a plausible working theory in explanation of phenomena which are at present only very imperfectly understood, but the importance of which increases almost daily. In saying this we must not be taken to mean that we agree with all that Dr. Reinhardt says. Whatever may be the ultimate end of the inquiry into mental processes, conscious or subconscious, Dr. Reinhardt has written an interesting work, and he seems to be both a successful hypnotiser and to have met with extraordinarily sensitive subjects.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., Professor ALEX. MACALISTER, Professor ARTHUR THOMSON, Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON. Vol. XLV. Third Series, Vol. VI., Part III. April, 1911. London: Charles Griffin and Co. Annual subscription, 21*s.*, post-free.—The April issue of the *Journal of Anatomy and Physiology* possesses the distinction that an unusually large number of its constituent papers deal with subjects which are of direct utilitarian interest in practical medicine and surgery. The charge that research in human anatomy tends nowadays to be confined to clearing up obscure problems of development or morphology receives direct refutation in the work which appears in this volume, for it is amply demonstrated that the investigation of normal adult anatomy may always take new and useful channels hand in hand with the advances made in the study of its cognate sciences. The injection of alcohol into the divisions of the trigeminal nerve has been the motive for the reinvestigation of the anatomical relations of these trunks by Professor J. Symington. His paper upon the Relations of the Main Divisions of the Trifacial Nerve is a study of the sectional anatomy of the head, carried out in order to provide safe guides for the proper penetration of the nerve trunks by the hypodermic needle. Normal regional anatomy is also dealt with by Mr. F. G. Parsons in his paper on the Form of the Parotid Gland, which is the outcome of the study of the normal form and relations of the formalin-hardened gland. The same author also contributes an article on the Reconstruction of the Norma Facialis and Verticalis of the Skull. The aims of the method adopted are to establish a sufficiency of measurements from a series of fixed points of the skull in order to enable a graphic representation of the skull to be reconstructed and compared with reconstructions of other skulls similarly produced. The simple production of an outline of the most important features of the skull from numerical data is a desideratum, for to most people the study of such a reconstruction yields more information than the study of a mere table of figures; it is the choice of the arbitrary points of measurement that is the problem upon which general agreement is somewhat difficult to obtain. A paper of great interest to the pathologist is that of Professor A. C. Geddes, which deals with the changes undergone by the bones in acromegaly, a subject to which anatomists have devoted much attention of late. Professor Geddes's paper has the great merit that it describes the actual changes in the skeleton of a case whose clinical history has been recorded from the onset of the disease to its fatal termination—a period which covers 25 years. The clinical features of the case have been recorded in the *Edinburgh Medical Journal* by Dr. G. A. Gibson, and the soft tissues are also described in the same journal by Professor Geddes; we therefore possess in these publications a highly detailed account of the progress and ultimate pathological

changes of this remarkable disease. The periodic photographs of the patient, showing the progressive nature of the process, are as striking a series of pictures as could well be imagined; and the detailed reports on the skeleton, which is to find a permanent resting-place in the University of Edinburgh, constitute a record of the inroads of this strange pathological process that cannot fail to be of great value. The same author also contributes notes on Anomalies of the Subclavian Arteries. The subject of the Relation of the Brachial Plexus to the First Rib and to Cervical Ribs has two papers devoted to it. Dr. T. Wingate Todd deals more especially with cervical ribs of surgical importance, and Dr. F. Wood-Jones with a case of rudimentary first ribs studied in relation to the nerve trunks. This subject is one around which an extensive literature is growing, and it is also one of obvious importance to the clinician as well as the pure anatomist. Developmental problems are dealt with by Mr. J. E. S. Frazer, the Pharyngeal End of Rathke's Pouch; and by Dr. R. J. Gladstone, a Case in which the Right Ureter passed behind the Inferior Vena Cava: with a Short Note upon a Case in which the Left Renal Vein passed behind the Abdominal Aorta, and the bearing of these Abnormalities on the Development of the Abdominal Veins. Two papers deal with osteology: Dr. Douglas E. Derry discusses the significance of accessory articular facets between the sacrum and ilium; and Dr. W. L. H. Duckworth describes a skull dredged from the North Sea. A paper on the Lamina Terminalis is contributed by Dr. J. Cameron.

Journal of Laryngology, Rhinology, and Otology. January to June, 1911. London: Adlard and Son. Price £1 per annum.—The articles contained in these numbers which are of special interest are the following:—Partial Petromastoid Excavation with Preservation of the Tympanic Membrane and Ossicles, by Georges Mahu (Paris), in the January number. Reports for the Year 1909 from the Ear and Throat Department of the Royal Infirmary, Edinburgh: A Clinical and Bacteriological Study of 36 Cases of Mastoid Suppuration, including 10 Cases of Intracranial Complication, by Dr. A. Logan Turner and Dr. F. E. Reynolds (with 2 plates), in the February, March, and April numbers. Injuries of the Head and Nasal Diseases, by C. Ziem, in the March number. Report of a case of Thrombosis of the Lateral Sinus Exhibiting Symptoms of Cerebellar Abscess; Operation; Recovery, by Mr. J. Walker Wood; and Fibrolysin in Otology, by Mr. P. M. Yearsley, in the May issue. The June number is unusually full of original matter, an article by Dr. James Adam, entitled "A Note on Turbinal and Sinus Function," being well worthy of study. The *Journal* contains besides these a large number of reports of the various throat and ear societies, with a few abstracts from current literature. This journal has now been handed over to a body of laryngologists and otologists, some 60 in number, who have taken over its control under the management of Dr. P. Watson-Williams.

PRIZES FOR LIFE-SAVING APPARATUS.—In 1907 the Council of the Royal Society of Arts offered certain prizes for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious. These prizes were offered in connexion with the Fothergill Trust, and the Council has now awarded gold medals to Mr. H. A. Fleuss and to Mr. W. E. Garforth, and silver medals to Mr. Richard Jacobson and to the Mining Engineering Company. The report of the committee which investigated the claims of the various applicants for the prizes is printed in the issue of the *Journal of the Royal Society of Arts* for June 16th, and contains some interesting details with regard to the adjudication of the awards.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are among the amounts received at the Mansion House up to June 26th:—

THE LANCET.

LONDON: SATURDAY, JULY 1, 1911.

The National Insurance Bill.

As is sufficiently shown in that small proportion of the numerous communications which we have received for which we are able to find space in our columns, the general feeling of the medical profession is that the National Insurance Bill in its existing shape is absolutely unsatisfactory; and we have chronicled, as has been done regularly in the daily press, the growth of the feeling among the members of the British Medical Association that the presentation to the Government of what is practically an ultimatum is absolutely necessary in the present position of affairs. The British Medical Association is now inviting every registered medical practitioner to sign an undertaking in the following terms:—

I, the undersigned, hereby undertake that, in the event of the National Insurance Bill becoming law, I will not enter into any agreement for giving medical attendance and treatment to persons insured under the Bill, excepting such as shall be satisfactory to the medical profession and in accordance with the declared policy of the British Medical Association; and that I will enter into such agreement only through a Local Medical Committee representative of the medical profession in the district in which I practise, and will not enter into any individual or separate agreement with any approved society or other body for the treatment of such persons.

At the same time, the members of the medical profession are asked to attest the following memorial to Parliament:—

(*a*) That Parliament and the Government should postpone dealing with all questions of arrangements with medical practitioners for attendance and treatment of the insured, whether under the head of medical, maternity, or sanatorium benefits, until such terms shall have been arranged as shall afford reasonable assurance that competent medical practitioners will be induced, in the necessary numbers, to enter into those arrangements for treatment of the insured which the proper administration of such benefits would require.

(*b*) That arrangements made under the Bill for medical attendance and treatment of the insured should apply to those persons only whose average income from all sources does not exceed £2 per week.

(*c*) That the Bill should be so amended as to provide that the administration of medical and maternity benefits, like that of sanatorium benefit, shall be placed entirely in the hands of the Local Health Committees, and not of the approved societies.

(*d*) That the Bill should be so amended as to provide that each insured person entitled to medical benefit shall have free choice of doctor from among those medical practitioners practising in the district who are willing to enter into arrangements under the Bill.

(*e*) That the Bill should be so amended as to provide that an adequate number of medical practitioners who have had experience of general practice among the classes from which the insured will chiefly be drawn shall be included amongst the Insurance Commissioners and in the Central Advisory Committee; that the number of medical practitioners on the Local Health Committees should be increased to at least one-fourth of the whole number; and that provision should be made for the constitution, in the district of each Local Health Committee, of a Local Medical Committee, representative of all the registered medical practitioners practising in the district, which Local Medical Committee shall be consulted on all questions of arrangements with registered medical practitioners for attendance upon the insured.

The answer to the invitations of the Association have been very satisfactory.

There is undoubtedly the difficulty in the memorial that it appears to consider the contract system, under which such terrible, almost devastating, abuses have arisen in many parts of the country, necessary to national insurance against sickness, while there is a very large and important section of the medical profession who believe that it is not so necessary, and that the time when the whole of the relations of the medical profession to the public are undergoing rearrangement offers a remarkable opportunity for taking up the position that, in spite of its numerous conveniences, the contract system is inimical to the public interest. Those who think in this manner hold, as we do ourselves, that the conditions of medical practice are sufficiently flexible, and the provisions of the National Insurance Bill sufficiently elastic, to allow the system of payment for work done to be recognised by the Government and adopted by the medical profession, at any rate in such localities where the majority of medical men find it to favour the public interest as well as their own. We cannot see that there is here any immediate parting of the ways—all find the Bill at fault. The statesman-like proceedings in the counsels of the British Medical Association, which have resulted in obtaining a measure of unanimity in favour of the contract system, might well, we think, in future negotiations with the Government be so far extended as to permit of organisations under Local Health Committees whereby the system of payment for work done would be adequately recognised.

But for such a complete readjustment of affairs time will be wanted, just as time will be wanted to ascertain what terms, under any system of contract practice, will secure that a sufficient number of competent medical practitioners can be induced to enter into contracts. The determination which is understood to exist in the mind of the Government to press the Bill through without delay is therefore to all medical men's thinking most unfortunate. Unanimity of feeling in the medical profession, whether particular members are likely or not likely to be affected by the passing of the Bill, is very great in respect of the necessity that the professional relations between medicine and the public should not be turned upside down in a hurry, and the responsibility of the Government in the matter is becoming proportionately heavy. The General Medical Council, which for some years has been seriously uneasy at the increased and increasing shortage of candidates for medical qualification, has adopted a weighty report of a subcommittee of its body, which states that under the Bill the existing relations of the majority of the members of the medical profession to the State and to the public will be profoundly altered. The report also expressed the belief that changes, "whose full effect it is impossible to forecast, will take place in the sanitary and preventive departments of public health administration." We believe that the Council is right, and these serious matters have not been dealt with in the reply of the Chancellor to the Council's report.[1] To very many of our readers the question of the figure at which a capitation fee

[1] THE LANCET, June 3rd, p. 1540, and June 24th, p. 1723.

under the contract system should be placed, or the line under such a system at which a wage limit should be drawn, are matters of the greatest import. Heaven knows we do not minimize the urgency of the threats contained in the Bill against the material prosperity of many of our readers, but we suggest that the risk to which the medical profession will be exposed under the provisions of the Bill, so far as they are outlined, is even greater than is indicated by the apparent intention of the Government to underpay the medical practitioners coöperating in the National Insurance scheme. The risk is that the whole status of the profession of medicine may be hopelessly lowered if too large a proportion of its work is administered at the dictates of lay committees; for on this it will ensue that the supply of candidates for professional qualification will decline in quantity and perhaps quality. It would be a national disaster that this should occur at a time when enormous developments in scientific medicine make it absolutely necessary that the State, through and with the aid of the General Medical Council, should maintain a high standard of medical education, an arduous curriculum, and a drastic system of examinations. We feel that every section of the medical profession will agree in believing that a powerful case has been made out for urging the Government in the strongest and most unmistakable terms to give adequate time to the discussion of these great problems. The powerful and solid resistance to the medical provisions of the Bill, which has been organised along certain lines by the British Medical Association, forms one excellent reason why the Government should take leisure to reconsider the position of the medical profession under the Bill. The growing opposition to the Bill in Ireland forms another. Further reasons will be found in the just apprehension of the General Medical Council and of the great medical corporations that the whole status of medicine, as a scientific profession, may be degraded by a measure which should call for the closest coöperation of scientific medicine. Medical opposition to the Bill is unanimous, and the many and various grounds for the professional attitude require time for their exposition.

The Coronation Ceremonies.

THE Coronation is over and we need not dwell upon the incidents of a gorgeous ceremonial, which was at once impressive with its reminiscence of feudal ceremonies and yet more intimate than anything which we associate as a rule with modern sovereignty. The daily newspapers have done full justice to the scene within the Abbey, to the passage of the KING and QUEEN to and from its portals, and to their prolonged progress on the following day when they passed through Temple Bar, receiving the loyal greetings of the City at the hands of its Lord Mayor, to journey south of the river into streets not familiar with Royal pageants and among people unused to be the direct recipients of Royal smiles. We congratulate King GEORGE and Queen MARY most heartily upon the part which they played during two days, and upon the warmth of the loyal greeting which acclaimed them at every step. The people among whom they passed had assembled in serried lines upon the footways for hours before—some of them since dawn—and they were subjects to be proud of, not less enthusiastic, orderly, and courteous than those who occupied stands and costly seats in the windows of clubs and the façades of palaces. The police, with a caution which was ample, but which it is ungrateful to suggest was exaggerated, had secured safety from all those dangers which are so difficult to eliminate when huge crowds assemble. It has been suggested that the absence throughout of any excessive crushing was due to the apprehensions that had been created by the erection of so many unyielding barriers at different outlets to and from the route. This may have been so, but, as no one can possibly guess either what amount of crowding there might have been or what tragedies might have ensued had no steps been taken to deal with the risks, we find room here for nothing but praise of the police regulations. It is an event of the highest medical importance that such a ceremony as the Coronation, which has stirred the imagination of hundreds of thousands of persons, has taken place with the absolute minimum conceivable of injury, illness, or inconvenience.

The notable absence of accidents and of temporary or serious cases of illness among the spectators both during the Coronation procession and during the Royal progress was principally due to two main causes—firstly, to the precautions above referred to as having been taken by the police, and secondly to the weather. If we say that the latter was practically ideal for such an occasion we are liable to be met by the suggestion that bright sunshine, or at least some more or less protracted gleams of it, would have added considerably to the brilliancy of the spectacle both within and without Westminster Abbey; and if the climatic conditions which greeted Their Majesties on June 22nd and 23rd had resembled those of the preceding week, undoubtedly the pageant would have gained in beauty. But no medical man thinking over the circumstances in which these enormous concourses of persons came together could fail to be glad that such ideal June weather as marked most of May was not granted. For ideal weather for public spectacular display and ideal June weather are not identical. Those who from the safe eminence afforded by stands or windows watched the intervention of the members of the St. John Ambulance Association, and applauded the energy of Boy Scouts or the good-natured sympathy of policemen in the few cases of fainting which gave them occasion to display their willingness to assist, possibly came to the conclusion that the provision for sickness was fully equal to, if not in excess of, the necessities of the day. And so it was, as matters turned out. But if there had been hot sun such as there was during the last week of May and the opening days of June the tale might well have been a different one. The front rows of the crowd at most points of prominent interest were composed of men and women of all ages, many of whom had spent the night at or near the spot where they stood. All had been standing erect in expectancy for three or four hours before the event which they awaited took place and had been the objects of an appreciable degree of pressure from their neighbours. They may not have been without

food or drink, but they certainly had foregone their usual meals in exchange for snacks, taken in circumstances which would hardly be recommended by a medical man. They assuredly had good cause to be thankful that they were not compelled to hold their hard-won places in the brilliant sunshine of a summer morning. Not dozens but hundreds or thousands would have needed the assistance awaiting them if the heat which prevailed till recently had continued but a short time longer, and we need hardly add that troops, police, and all engaged in the exacting duties connected with the ceremonial would have suffered severely. As it was the long processions with protracted standing at attention varied by Royal salutes, were fairly trying for the soldiers who had marched early from their tents in the various parks, and those who watched them must have noted how glad they were to shift their positions and bend their heads when the order to "stand at ease" was followed by "stand easy."

It certainly was an excellent crowd, of a composition which reminded the observer of the changed conditions prevailing in all London throngs, whether they await the opening of pit doors or the passing of Royal processions. Is it the feminine influence which has made itself felt, or have the improved courtesy and forbearance of men of their own social class, and indeed of all classes, rendered it possible for women and young girls, gentle and refined, but at the same time self-reliant and independent, to pass long hours of waiting by night or day on kerbstones and pavements, and to retain their places secure and undisturbed? For anyone who remembers the crowds of a bygone generation, as when Queen VICTORIA celebrated her Jubilee in 1887, or upon minor and earlier occasions, the advance is remarkable. The crowd that witnessed the illuminations in the City and in Piccadilly on Thursday night was in places rather larger and more congested than was agreeable for those who found themselves involved in it, and at times the situation was rendered worse by the senseless rushes made by gangs of stupid lads. There was, however, the same absence of serious accidents that distinguished the proceedings by day, and the same gratifying fact that cases of over-indulgence in alcohol were extremely rare. At eight London police-courts a total of less than 300 charges described as arising out of the Coronation were heard, a large proportion of which were of drunkenness, the majority of the defendants in these being women. On such occasions excitement accounts for a good deal, and those of both sexes who behaved foolishly in their cups were certainly inconspicuous. Here, again, comparison with the "festive" occasions of 20 or more years ago shows a marked improvement in manners in the present generation.

Among those who had good reason to be thankful for the absence of intense heat upon the days of ceremonial were Their Majesties the KING and QUEEN. Theirs, be it remembered, were the leading parts, in fact and not merely in name, in the great ceremonial of their Coronation, parts which they had to sustain for long hours with the eyes of thousands at all times concentrated upon them, watching every gesture, noting eagerly every smile from the moment when they left Buckingham Palace early in the morning of their Coronation Day until their return in the afternoon. They had to support the strain, mental and physical, of a ceremony the solemnity and deep import of which would have rendered it a fatiguing ordeal even if it had not been preceded and followed by the drive at foot's pace amid the ceaseless din of loyal enthusiasm. Royal robes and crowns are not garments of choice by those who would be comfortable. To smile and bow incessantly while facing a restless sea of waving hats and pocket-handkerchiefs, amid ceaseless cheering through a space of more than two hours, is a task all would find hard. We congratulate Their Majesties upon their famous endurance of the physical strain of the Coronation ceremonies, and pray that the vigour of health so publicly demonstrated may be theirs for many long years.

Auto-inoculation in Pulmonary Tuberculosis.

THE doctrine of immunity has had far-reaching results in its applications to the treatment of infections, and has brought new light in regard to many obscure and difficult problems in the pathology of acute and chronic disease processes due to microbial and protozoal agencies. The study of the cellular and humoral responses to sublethal doses of bacteria or their toxins has revealed some of the details of the mechanism by which complex multicellular organisms are enabled to combat these disease-producing agents successfully. It is now generally recognised that these protective processes are capable of destroying the infecting organisms, of limiting their activities to local disturbances, or, if the organisms become generalised, of neutralising their effects and eventually producing a more or less permanent protection in some cases. On the other hand, if the organisms are extremely virulent, or if the protective processes are ineffectively activated, the infection progresses unchecked and death eventually occurs. It is obvious that the bacteria, either directly or through the agency of toxic products, bring into action the protective mechanisms, and that the effective character of these immunising responses is related to the dose and degree of virulence of the infecting organism. The phenomena of chemiotaxis, of phagocytosis, and of the development of the numerous antibodies which have been demonstrated in the blood and tissue fluids, all afford striking evidence of the mutual reactions which occur between the invading agent and the organism it attacks. In experimental infections in animals the infecting dose can be nicely graduated, and the virulence of the organism can be varied so that any condition can be produced, from a slight and strictly localised lesion with no general manifestations, to a condition of profound septicæmia, with generalisation of the bacteria and their products, marked intoxication, and certain death. It is difficult to avoid the conclusion that the similar variations seen in natural infections in man depend upon like conditions, and the theory of auto-inoculation, enunciated by Sir ALMROTH WRIGHT and his collaborators, is based upon these considerations and upon the interesting observations of Dr. J. FREEMAN in regard to the effects of massage upon localised bacterial infections, whereby it was shown that active and passive movements led to variations in the

opsonic index of the patient to the organism concerned These results have been confirmed and extended by numerous observers, so that it would appear as if any condition tending to alter the local vascular supply, such as massage, active and passive movements, the induction of hyperæmia by BIER'S method, and the administration of the X rays, may all lead to an increased discharge of bacteria or their products from the local lesion into the general blood stream, and therefore be said to produce auto-inoculation. According to Sir ALMROTH WRIGHT, the different effects of bacterial infections may be satisfactorily explained on this theory. He suggests that generalised infections are characterised by frequent or even continuous auto-inoculations, that strictly localised infections do not give rise to them at all, while that in a third class, in which the infection is more or less localised, occasional auto-inoculations occur depending upon variations in the local blood- and lymph-supply.

Treatment by means of bacterial vaccines is an attempt to utilise the information at present available in regard to the nature of immunity by the administration of graduated doses of bacterial products with a view to increasing the production of antibodies. The work of Sir ALMROTH WRIGHT has served to extend widely the use of vaccines and to afford an intelligible explanation of their action, while determinations of the opsonic index supply in some degree a means of measuring the immunising responses evoked. It is of interest to note that the determination of the opsonic index of the blood before and after massage of an infected area has shown that the immunising responses, induced by the auto-inoculations thus set up, are strictly comparable to those obtained by inoculation with bacterial vaccines prepared from the organism concerned, and that the results of such auto-inoculations may be beneficial or harmful according to their degree. It is not surprising, therefore, that attempts have been made to control auto-inoculations with a view to treatment—in other words, to utilise the patient's own bacterial products rather than to inject others obtained outside the body. We have received a copy of a thoughtful, suggestive, and original book by Dr. M. S. PATERSON,[1] in which this question is discussed in regard to the treatment of pulmonary tuberculosis by rest and graduated labour. It is of interest to note that Dr. PATERSON worked out his scheme of treatment before he was aware of the theory of auto-inoculation, and that his championship of this depends upon the explanation it affords of the results he has obtained. He describes how he conceived the idea of putting patients to do work involving the use of the upper limbs as well as the lower, supposing that this might possibly exert a more direct influence upon the lungs. He found that suitable patients could perform the hardest manual work with improvement in their general condition and weight, with a decrease in the quantity of sputum, and without the occurrence of hæmoptysis. He then observed that some patients who made no progress on lighter work showed marked improvement when put upon a harder grade, and also that some patients who had slightly over-exerted themselves and developed a small rise of temperature were subsequently none the worse; indeed, they were sometimes much better and were able to resume the same grade of work without ill-effect. It was also found in the case of certain patients, who over-exerted themselves considerably against advice, that headache, fever, loss of appetite, and sometimes pleurisy resulted. On learning from Dr. A. C. INMAN of the theory of auto-inoculation Dr. PATERSON applied it to these results, and after numerous determinations of the opsonic index of the blood of his patients by Dr. INMAN, they came to the conclusions that physical exercise induced auto-inoculations, and that systematic graduation of exercise regulated and controlled the extent of these auto-inoculations. Dr. PATERSON now gauges the progress made by his patients by a careful study of the temperature, the sputum, the patient's own feelings and appetite, and by the body-weight, and he gives as his aims of treatment the raising of the patient to his normal or highest known weight, and the elevation of his specific resisting power to such a degree that he can perform the hardest work without the risk of introducing a dose of bacterial products into the blood large enough to produce constitutional disturbance. The control of the auto-inoculations is therefore one of the great objects of the rational treatment of pulmonary tuberculosis, if the theory of auto-inoculation is accepted as the explanation of the phenomena of the disease and of the effects of rest and exercise. In febrile cases the auto-inoculations are excessive, and must be reduced by appropriate means.

Dr. PATERSON maintains that the most effective and most rapid method of securing this object is by what he has termed complete immobilisation, which consists in absolute rest in bed, the patient being treated like a case of enteric fever, except in the matter of diet. He is not allowed to move in bed, to read, to wash himself, to cut up his food, or to go to the lavatory, while every means is employed to lessen ineffective or unnecessary coughing. Interesting charts are shown in the book illustrating the effects of some of these movements upon the temperature. In afebrile and localised cases, and in cases in which the excessive auto-inoculations have been controlled the inducement of effective auto-inoculation by graduated exercise is the principal factor in treatment. With this object in view Dr. PATERSON has elaborated at the Brompton Hospital Sanatorium at Frimley, where his observations have been carried out, six grades of labour, with a preliminary period of walking exercise. He gives details of these grades and of the various guides for determining when a patient shall be changed from one grade to another. He pays particular attention to the temperature chart and believes that a temperature of 99° F. in a man or of 99·6° in a woman, accompanied by headache and loss of appetite, are indications of over-inoculation. These patients, after a few days of complete immobilisation, can often return to the grade which caused the over-inoculation without difficulty. Some patients have to pass through several grades before they obtain effective auto-inoculations, and this is the explanation offered of the observation previously mentioned—that some patients who make no progress on light work advance satisfactorily

[1] Auto-inoculation in Pulmonary Tuberculosis. By M. S. Paterson, M.B., B.S., M.R.C.S., L.R.C.P., Medical Superintendent at Brompton Hospital Sanatorium, Frimley, &c. London: James Nisbet and Co. 1911. Pp. 236.

when put upon a harder grade. Dr. PATERSON'S suggestions and his explanations of his results are of great interest and are worthy of careful consideration. The system of graduated labour as applied to the treatment of pulmonary tuberculosis has many obvious advantages: it tends to improve the physical condition of the patient, and to render him ready for work directly he is discharged with his disease arrested; moreover, it brings a more definite interest into the treatment than where the only exercises prescribed are graduated walks. The theory of auto-inoculation must, of course, be regarded only as a working hypothesis, but Dr. PATERSON'S interesting observations, although not a direct outcome of this theory, lend considerable support to it, and should serve to encourage the application of similar methods to other infections. We congratulate him upon his work.

Annotations.

"Ne quid nimis."

IMPROVEMENTS IN THE NAVAL MEDICAL SERVICE.

WE understand that the recommendations of the Committee on the Naval Medical Service, which has been presided over by Vice-Admiral Sir John Durnford, have been accepted by the authorities practically in their entirety. Under the new conditions of service the inducements to young medical men to join will be distinctly greater. There are increases of pay in certain directions, provision is made for acceleration of promotion in response to good and scientific work, and the facilities for post-graduate study are multiplied. The projected reforms affect also Queen Alexandra's Royal Naval Nursing Service, where the age of entry has been raised and the rates of pay increased, and the Sick Berth Staff, where alterations for the better have been made in training, and where special allowances will be granted for the discharge of exceptional duties. We desire to bring this information prominently before those of our readers who are connected with medical schools, for they will find in the report when it is issued many reasons for suggesting to young qualified men that the career of the naval medical officer contains excellent opportunities.

HOSPITAL SATURDAY FUND: A CORONATION APPEAL.

"IN view of the Coronation, and having regard to the fact that His Majesty has recently become Patron of the Hospital Saturday Fund, the time is felt to be opportune for a special appeal on behalf of the work which that Fund is doing amongst the hospitals of London." These opening words of a circular letter signed by Sir Savile Crossley and Mr. A. W. Davis, respectively chairman and secretary of the Fund, will probably meet with a good response. The great interest which His Majesty has always evinced in the hospitals is well known, and Coronation year could not be more fittingly commemorated by the charitable than by increased provision being made for the ever-growing needs of hospital work. The suggestion in the circular was that those who now contribute regularly to the Hospital Saturday Fund should double their weekly contributions in Coronation week as a special offering. We join Sir Savile Crossley and Mr. Davis in cordially commending the idea to contributors, and remind them that though Coronation week has passed the opportunity for generosity remains.

SCIENTIFIC RESEARCH FOR THE LOCAL GOVERNMENT BOARD.

THE President of the Local Government Board has authorised the following special researches to be paid for out of the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease:—

1. A research into the causes of premature arterial degeneration in man, by Dr. F. W. Andrewes, pathologist to St. Bartholomew's Hospital.
2. An inquiry by Dr. J. H. Thursfield, of St. Bartholomew's Hospital, into the causes of death in measles.
3. A comparison by Professor Nuttall, F.R.S., Quick Professor of Biology at the University of Cambridge, of the number and kind of fleas found on rats.
4. A continuation by Dr. C. J. Lewis, of Birmingham University, of his investigation into the degree of prevalence and the characteristics of micro-organisms known as non-lactose fermenters in the alimentary canal of infants.
5. An investigation into the same subject by Dr. D. M. Alexander, of Liverpool University.
6. An inquiry by Dr. Graham Smith, of Cambridge University, into the incidence of non-lactose fermenters in flies in normal surroundings and in surroundings associated with epidemic diarrhœa.
7. A study by Dr. F. A. Bainbridge, of the Lister Institute, of the anaërobic bacteria in the alimentary canal of infants.
8. An investigation by Dr. Graham Smith into the possibility of pathogenic micro-organisms being taken up by the larva and subsequently distributed by the fly.

TUBERCULOUS BURSITIS.

TUBERCULOUS bursitis has not received much attention In the *Johns Hopkins Hospital Bulletin* for May Dr. Sydney M. Cone has described two interesting cases. A man, aged 22 years, was admitted into hospital complaining of pain in, and loss of function of, the right shoulder. He had always been strong and healthy, and there was no family history of tuberculosis. For about three years the right shoulder had been stiff on getting up in the morning, but this wore off after he had worked. For the past three months the shoulder had been constantly painful. The pain was increased on movement and prevented him from working. Examination showed fulness of the shoulder, especially over the coracoid process, and crepitus was felt in front of the joint. There was localised tenderness at the acromion process. He could not raise the arm or place it behind him because of the pain. Radiography showed rarefaction over the tuberosity of the humerus and slight roughening there as well as at the upper part of the glenoid fossa. Two milligrammes of tuberculin were injected subcutaneously and produced a reaction locally, focally, and generally. At the site of the injection there were swelling, tenderness, and redness. On the following day there was pain in the shoulder and the temperature rose to 100° F. On August 2nd, 1909, an incision was made from the acromion process outwards and downwards towards the deltoid insertion. The deltoid muscle was divided and a thick grey sac was exposed by blunt dissection. As there was difficulty in removing the sac in consequence of adhesions it was incised and about 400 facetted bodies shot out with a thin serous fluid. The sac was then removed without difficulty. An incision was made into the joint at the point of greatest adhesion near the tuberosity. The joint was found to be normal. The muscle was sutured, the wound was closed, and union took place by first intention. On Sept. 8th he was readmitted with a sinus in the line of incision. This closed under treatment, but others formed. On Jan. 24th, 1910, the apices of both lungs

were found to be tuberculous. He was sent to the country. He there improved much, and on Oct. 15th the sinuses had all closed and he was able to use his arm. The sac measured 11 by 6 by 3 centimetres. Its wall varied in thickness from 3 millimetres to 1½ centimetres and was grey with pinkish areas throughout; there were some nodular areas. Sections from many portions of the sac showed typical tuberculosis—dense fibrous tissue containing areas of small round cells, epithelial cells, giant cells, and caseation. In places there were single and conglomerate tubercles. The facetted bodies were found on microscopic examination to consist of granular loculated material staining with Weigert's fibrin stain and showing flakes, granules, and strands. Tubercle bacilli were found by the Ziehl-Neelsen stain. In the second case, a man, aged 24 years, came under observation on Feb. 18th, 1910. He had had a swelling over his left patella for several years which gave him no trouble. On Nov. 27th, 1909, he fell on the knee, and two days later it began to be painful. He was well developed and otherwise normal except for a tuberculous focus at the apex of the right lung. The left knee was tender, and larger and warmer than the right. Over the patella was an elastic lump of the size of a hickory nut, freely moveable under the skin. The tuberculin test was positive. The knee was opened and pinkish-yellow tags were removed. After closing the joint the prepatellar bursa, which formed a dense fibrous mass, was excised. The wounds were closed. An active tuberculous process developed in the joint and surrounding tissues, necessitating amputation. The prepatellar bursa formed a solid glistening white mass, which cut with difficulty and showed greyish softer areas here and there. Microscopically it showed islands of small round cells, epithelioid and giant cells, and caseous areas. The material removed from the joint showed active tuberculosis. These cases illustrate the two types of tuberculous bursæ which have been described in recent years by continental writers, one containing rice bodies and the other of a sclerosing form.

THROMBOSIS OF THE SUBCLAVIAN VEIN IN MEASLES.

IN the *Glasgow Medical Journal* for March Dr. A. J. Couper has reported a case of a very rare complication of measles—thrombosis of the subclavian vein. A well-nourished but flabby boy, aged 18 months, had measles. The heart sounds were soft and the pulse was of low tension. Mucous râles were heard over the lungs. The rash faded on the fifth day, but the temperature, previously normal, rose to 102° F. During the next three days it fell to normal. On the sixteenth day the temperature again rose to 102°, the pulse to 136, and the respirations to 44. On the following day the temperature was 97·6°, and the dorsum of the right hand was swollen, but the circulation in the part was good, and there was no pain. On the next day the swelling was much increased, involving the palm and extending up the wrist. The circulation in the fingers was sluggish, and the terminal phalanges were cyanosed. On the nineteenth day the whole of the right arm and the inner wall of the axilla were œdematous and very tense. The limb was cold and mottled with purple, and the ends of the fingers were black. Crepitant râles were heard at both bases posteriorly, but there was no dulness. On the twentieth day the swelling was still further increased, the limb and inner wall of the axilla had assumed a much deeper and more uniform colour, and there were numerous bullæ containing sero-sanguinolent fluid. The child died on the following day. At the necropsy the right arm was found swollen to about twice the size of the left. It was of a purple colour, which was most marked towards the distal extremity. The inner wall of the axilla was livid and swollen. On incision the subcutaneous tissue was found to be very œdematous. The axillary and subclavian veins were engorged. In the subclavian, about half an inch from its proximal end, was a firm adherent clot which extended for an inch backwards. Attempts to grow cultures from the clot failed. There were numerous enlarged axillary glands, but none were caseous or impinging on the vein. During life the swelling of the hand and the flabby heart caused thrombosis to be suspected. The involvement of the axilla indicated that the lesion was without the limb. As the subclavian is one of the valved veins it was thought that the clot was situated in it. No case of thrombosis of the subclavian vein in measles appears to have been previously recorded, but thrombosis of the renal veins and of the cerebral sinuses has been observed.

THE OSTEOLOGY OF THE BUSHMEN.

THERE has been added lately to the Museum of the Royal College of Surgeons of England an extensive collection of skeletons of Bushmen which will prove of great interest to those engaged in the study of the pigmy races of mankind. Along with other specimens added during the last 12 months these skeletons will be on exhibition in the council room of the College on Thursday and Friday, July 6th and 7th, from 10 A.M. to 5 P.M., and on Saturday, the 8th, from 10 A.M. to 1 P.M. This special exhibition is open, as is the Museum itself, to all medical men, and the services of the museum staff are freely at the disposal of visitors. The outstanding feature of the Bushmen, besides their small size and negroid traits, is the juvenile character of the adult skeletons. The Bushmen are in one sense adult boys. One of them shows a remarkable instance of toleration of injury. The upper teeth have ground the food against the alveolar border of the lower jaw until the inferior dental nerve has been freely exposed on the grinding surface. At the annual exhibition numerous additions to the pathological collection, to the series of malformations, to the series of human anatomy, and especially to prehistoric British races, will be on view.

BRACHIAL NEURITIS CAUSED BY PRESSURE OF FIRST RIB.

THE symptoms occasioned by the presence of a supernumerary or cervical rib are now well recognised, and there is excellent reason to believe the condition is more frequent than is commonly supposed. Many patients whose symptoms are diagnosed as acroparæsthesia are found on X-ray examination to be suffering from cervical rib. In any case where the practitioner is consulted because of paræsthesiæ or radiating pains in the arm and hand, particularly if they are referred to certain fingers, where the subjective symptoms are aggravated by muscular effort, such as by the repetition of any occupation movement or movements, and where there may be slight objective impairment of sensibility in the fingers and slight wasting of the thenar eminence or of the radial interossei, he should always have recourse to a radiographic examination, for such symptoms are highly characteristic of cervical rib. A greater rarity, but one, nevertheless, of considerable practical importance, has been described by Mr. Thomas Murphy, surgeon to St. Vincent's Hospital in Melbourne, in the *Australian Medical Journal* for October of last year. His case exemplifies the inadequacy of such a diagnosis as "brachial neuritis" in certain instances and the desirability of radiographic investigation in all. The patient was a young woman aged 28 who complained of numbness, pain, coldness, and tenderness of the left upper extremity, with loss of power in the forearm and hand. The symptoms were always worse after any

exertion involving the use of the arms. They had continued for no less than seven years, varying considerably from time to time. On examination the arm, forearm, and hand were found to be painful on pressure throughout their whole extent. There was no localisation to any particular nerve. The hand and wrist were somewhat swollen and bluish, but no œdema was present. The patient could not close her hand. There was impairment of sensibility in the hand and some wasting of the forearm. On pressure over the brachial plexus just behind the sterno-mastoid there was a point of resistance, with marked tenderness and pain shooting down the arm. The neck was skiagraphed as a cervical rib was suspected, but this apparently was not present. Operation was decided on because of the tenderness and resistance in the neck. When the brachial plexus was exposed it was found that the nerve trunks were stretched over the insertion of the scalenus muscle into the first rib. The scalenus was divided near its insertion, and a considerable portion of the rib resected. Within a few hours of the operation the patient herself remarked that the hand was already normal in colour, instead of being bluish. In a week's time voluntary power had returned in the hand and the pain had entirely disappeared. The cure was perfect and permanent; the patient can now indulge in various forms of muscular exertion, such as typewriting, without any pain whatever. Previously such movements were impossible. A second skiagram showed definitely that it was the first thoracic rib which had been the offending rib. The main symptoms in the case appear to have been due to the effect of the contracting scalenus on the stretched nerve trunks where they passed over the prominence made by the insertion of the muscle into the bone. The circumstances under which an apparently normal first rib can cause severe nerve symptoms are not made quite clear in the case, but the importance of complete investigation of chronic cases of this nature is impressed on us by a perusal of this interesting communication.

ZINC IONISATION IN LUPUS VULGARIS.

AS our columns show, ionisation, or the introduction of drugs into the system by electricity, is coming much more into vogue and gives satisfactory results in many conditions. In THE LANCET of April 22nd Dr. J. Curtis Webb reported encouraging results from the treatment of colitis and proctitis by ionisation of a solution of zinc sulphate introduced into the bowel. In a recent number of the *Liverpool Medico-Chirurgical Journal* Dr. G. G. Stopford-Taylor and Dr. R. W. MacKenna have reported good results from the treatment of lupus vulgaris by ionisation of the same salt. Some years ago Dr. Stopford-Taylor ingeniously suggested a plan whereby the electric current might be concentrated on lupus nodules. The horny layer of the epidermis offers considerable resistance to the passage of the current, and if there is any break or abrasion of the epidermis the current tends to concentrate there. Lupus nodules are covered with ill-developed epithelium which is less resistant to the action of liquor potassæ than the surrounding healthy skin. If, therefore, the part to be treated is briskly rubbed over with a pledget of cotton-wool soaked in liquor potassæ the lupus nodules are denuded of their epithelial covering and appear as moist gelatinous masses embedded in the skin. The part is then thoroughly wiped with dry absorbent wool, and two or three layers of lint or a thick pad of cotton-wool, soaked in a 2 per cent. solution of zinc chloride or a 10 per cent. solution of zinc sulphate, are applied. The pad should exactly cover the part. Over this is placed a zinc electrode, which is firmly pressed on and is attached to the positive pole of a battery. The indifferent electrode is a pad soaked in a solution of sodium or ammonium chloride, and is applied to some distant part of the body and connected with the negative pole. The current is obtained from the ordinary galvanic battery of 12 or 24 cells, from accumulators, or from the electric mains through a switch-board. If the current is obtained from an ordinary galvanic battery or accumulator, a rheostat to graduate the intensity of the current, and a milliampèremeter to measure it, are required. The current is switched on gradually, as any sudden alteration in strength is likely to cause painful shock. The intensity to be aimed at is from 2 to 3 milliampères for each square centimetre of surface, which most patients can bear. The duration of the sitting should be from 10 to 20 minutes, but may be less if the patient cannot bear so much. The current should be switched off gradually. On removing the pad every lupus nodule is found converted into a dry glazed whitish plug. Where the skin is not broken there is no evidence of the passage of the current. After removing the electrode a burning sensation is felt, and after an hour or two there are considerable swelling and redness of and around the part treated. From the surface denuded of epithelium serum slowly exudes and dries into a crust, which should not be disturbed. All that is necessary is to apply a calamine or lead lotion. In about a fortnight the crust falls and considerable improvement is seen. Some of the nodules have completely disappeared, others are smaller, and all are more or less superficial. The treatment should be repeated every fortnight until the disease has completely disappeared. The ultimate result is a smooth, pliable, and elastic scar. The curative effect is due to several factors: (1) Zinc ions are powerful germicides; (2) they have strong coagulating drying properties; (3) as a result of the œdema produced by the current, which may last for several days, serum laden with opsonins and phagocytes comes into contact with tubercle bacilli in the nodules. For lupus vulgaris, in which the nodules are discrete, Dr. Stopford-Taylor and Dr. MacKenna have found the treatment superior to any other in speed, efficacy, and scar. They obtained remarkable successes in extensive lupus which had been treated by X rays, Finsen light, or other methods with great improvement, but had persisted in the form of a few scattered nodules. Such nodules may at any time become foci of fresh extension and are best treated by zinc ionisation. The treatment may also be applied with great advantage to lupus of the mucous membrane of the lip or nose.

BRITISH DENTAL ASSOCIATION.

THE annual meeting of this association will be held on August 3rd, 4th, and 5th at the University of London, South Kensington, S.W. The Museum Committee requests for this occasion the loan of specimens illustrating affections (infections and growths) of the periodontal membrane. Specimens, dry or wet, should be accompanied, when possible, by histories, microscopical slides, culture tubes, drawings, photographs, and radiographs, and should bear the name and address of the owner, in which circumstances the committee will hold itself responsible for the care of any specimens lent, and will return the same immediately after the meeting. The following classification will probably be adopted:—

Sites and modes of periodontal infection or growth:—
(1) In membrane itself.
(2) By extension from:—
Gingival margin.
Tooth { Apical region. / Cemental region (trauma).
Bone.
Secondary changes in membrane, gum, tooth, bone, and in more remote parts—e.g., mucous membrane, lymphatic glands, antrum, &c.

These willing to lend specimens are requested either to communicate with, or forward, not later than July 27th, the specimens

to the honorary secretary of the Museum Committee, Mr. F. Coleman, 129, Harley-street, London, W.

THE election of two members of Council will take place at a meeting of Fellows of the Royal College of Surgeons of England to be held on July 6th. Mr. Dent and Mr. Makins, whose terms of office have expired, will submit themselves for re-election, and a third candidate, Mr. B. G. A. Moynihan of Leeds, is announced.

THE governors and medical staff of Guy's Hospital will hold a garden party at the hospital on Tuesday next, July 4th, at 3 P.M. The medals and prizes will be distributed to the students by the Right Hon. Alfred Lyttelton, K C , M.P. The laboratories, museums, college, the Henriette Raphael Nurses' Home, and wards will be open to inspection from 3 to 5.30 P.M., and music will be provided in the grounds.

RESEARCH DEFENCE SOCIETY.

THE annual general meeting of the Research Defence Society was held on June 19th in the library of the Royal College of Physicians of London.

There were present among others Lord Cromer (in the chair), the Duke of Wellington, Sir Thomas Barlow, Dr. F. W. Sandwith, the Hon. Sydney Holland, Lady Dorothy Nevill, Admiral Fremantle, Sir Charles Cuffe, Sir Hugh Bell, Colonel Gordon, Lord Claud Hamilton, Sir Henry Knollys, the Bishop of Oxford, Professor Leith, Sir Frederick Treves, Sir Frank Lascelles, Sir Frederick Macmillan, Mr. Anthony Hope Hawkins, Sir James Reid, Sir James Dewar, Mrs. Garrett Anderson, the Master of the Temple, and Sir David Ferrier.

Mr. HOLLAND read the report. He then referred to the increase in the numbers of the society and to the work of the past year. He went on to speak of the antivivisection shops lately opened in London, and said that it was shameful that these shops should exhibit stuffed animals, put in position for imaginary experiments, without saying that no operation was permitted on any animal in this country unless the animal was under the influence of an anæsthetic. He pointed out that these shops must have a very demoralising effect on the minds of children. He added that such exhibitions helped the work of the Research Defence Society, for the society took occasion to distribute truthful leaflets and pamphlets outside the shops. Mr. Holland went on to speak of the way in which the society had kept the public informed of the facts of the case. He quoted with special approval a paragraph from Major Marjoribanks's pamphlet, "Friends of Animals," published by the society.

Dr. SANDWITH presented the honorary treasurer's report.

Sir FREDERICK TREVES moved the adoption of the report. He said that the last 25 or 30 years had witnessed an advance which in magnitude and in value of results had never been approached since healing became an art. It had proved a revolution rather than an advance, for such had been the nature of this progress that the very foundations of pathology had been overturned, old faiths had been swept to the winds, the assumed limits of philosophical inquiry had long been passed, while the capabilities of treatment had been so wonderfully expanded as to be worthy of the chambers of health in the New Atlantis. This great advance had led to the saving of innumerable lives, to the relief of unmeasurable pain, and to the providing of a cure for a series of diseases which were but a short while since regarded as beyond hope. This progress had been in the main accomplished by experiments on animals. More than that, without such a method of research the present measure of success could never have been attained. These experiments had not only led to a widely extended knowledge of the general processes of disease, but they had had an immediate, wide, and beneficent effect upon practical medicine. Methods of diagnosis had been rendered simple and exact. Methods of treatment hitherto undreamed of had been made possible, and not only possible, but safe and successful. In the relief of the sick the empiricism of ancient days had been replaced by proved and standardised methods, while the hesitancy and speculation which often attended the employment of new remedies had given way to a confidence based upon precise research. So striking and valuable had been the results of that line of inquiry with which this society was directly concerned that it was unnecessary at the present day to give specific instances to enforce the fact; but it was hard to resist the temptation of referring to the incalculable services which experiments on animals had rendered in the investigation of sleeping sickness. It would be interesting to know what measures the opponents of research would advise if experiments upon animals were to be excluded from an inquiry so urgent and so essential to the saving of human life as this. In view of the sterling and profitable advance which had taken place in all departments of medicine it seemed strange that a society should be needed to defend the methods of research upon which that advance had so conspicuously depended. If there ever was an occasion when it could be claimed that the end had justified the means, it was surely such an occasion as was now under notice. The society had been able to enlighten the public mind on the subject of modern medicine, to make intelligible the difficulties that had been encountered, the elaborate means by which these difficulties had been overcome, and the priceless benefits to humanity which had resulted from the research involved. In conclusion Sir Frederick Treves quoted a parable from Edmund Burke: "Because half-a-dozen grasshoppers under a fern make the field ring with their importunate chink, whilst thousands of great cattle, reposing beneath the shadow of the British Oak, chew the cud and are silent, pray do not imagine that those who make the most noise are the only inhabitants of the field, or that they are other than the loud and troublesome insects of the hour."

Mrs. GARRETT ANDERSON seconded the adoption of the report. She referred to the amount of the society's work, as shown by 150,000 papers distributed during the year, and 90 addresses and lantern lectures given. She said that it was extraordinary that research should need to be defended; but this need was due to "uninstructed conscientiousness," that bane of the world's progress. Evil-disposed people were comparatively few, while the ignorant were the great majority. In this case, more than in most, the ignorant thought they knew. Mrs. Garrett Anderson referred in feeling terms to the death of Sir Rubert Boyce, who had done such great work for the advancement of the University of Liverpool, and for the advancement of the knowledge of tropical diseases.

Lord CROMER then delivered the Presidential address. He said: In considering the position which our society occupies to-day it should, I think, be borne in mind that in the process of what I may call educating the public mind, the scientists, confident in the benevolence of their intentions, and secure in the uprightness of their cause, allowed the antivivisectionists to get a long start of them—an advantage of which, naturally enough, they were not slow to avail themselves. It was only three years ago that we all fully perceived that a humanitarianism, laudable, indeed, in its primary object, but, as we think, misdirected in its methods of action, and ill-informed as regards the true facts of the case, was really threatening the advance of a science which is itself eminently humanitarian in a different, and, I firmly believe, a higher and more rational sense. The reports which we have heard read afford, however, abundant proof that no effort has been spared during the last three years to make up for lost time. The number of our subscribers has been steadily increasing. Progress has, in fact, been satisfactory, a result we owe in a great measure to the untiring perseverance of our indefatigable secretary, Mr. Stephen Paget, to our treasurer, Dr. Sandwith, of whose unselfish labours I cannot speak too highly, and to our able assistant secretary, Miss White. Upon the somewhat numerous occasions when I have publicly pleaded the cause of our society I have heretofore generally dwelt more especially upon the magnificent results which have so far been achieved by the experimental method in the direction of saving the lives and preserving the health both of human beings and of animals. I do not propose to dwell on that branch of the subject now. In this respect our case has, I venture to think, been proved up to the hilt. On the one hand, all this mass of evidence goes to confirm the conclusion which I give on the high authority of Lord Rayleigh, the President of the Royal Society, that "the main cause of the remarkable development of science in modern times has been the adoption of the experimental

method of investigating nature." On the other hand, abundant proof has been adduced, by Dr. Dudley Buxton and other high experts in anæsthesia, to show that the experiments on living animals are generally painless, and are always conducted in this country with a due regard to the paramount necessity of inflicting a minimum amount of suffering. I do not, therefore, propose to say anything more on this branch of the subject. I will, however, ask you to bear in mind that the objects which our society seeks to attain are twofold. We wish not only to point to the results which have been obtained by the experimental method, but also to make known the facts as to experiments on animals in this country, and the regulations under which they are conducted. That I consider a most important object. It is important because we have to recognise that there are a considerable number of distinguished men and women in this country who, it may readily be admitted, are animated by very high moral sentiments, and who, in more or less decisive tones, condemn our proceedings. They represent an aspect of the case which not only demands fair consideration, but which, in so far as the general principle involved is concerned, will, I feel assured, excite the active sympathy of all civilised human beings, whether scientists or those less versed in scientific mysteries. I have said that the general principle advocated by our opponents is of a nature to command our respect and sympathy. I cannot always say as much for the methods which are at times adopted to enforce the validity of that principle. Our opponents may, I think, be divided into several different categories. Let me first deal with that which, as I venture to think, cannot legitimately claim either respect or sympathy. I allude to those who distort facts, and who wilfully calumniate the whole of a noble profession with a view to holding its members up to the unmerited odium of an ill-informed public. What can one say of those who resort to such ignoble methods as these to prove their case? Only this, I think, that it would be beneath the dignity of the profession which they attack to defend itself from such infamous charges, and that the arguments of those who can stoop to the adoption of such methods are wholly undeserving of consideration. Now I pass to another category of opponents, who, although I think they adopt an ethical standard which is both irrational and practically unattainable, are, at the same time, much more deserving of respect than those to whom I have previously alluded. I take as an example of this category the evidence given before the Royal Commission by a very worthy clergyman, the Rev. Lionel Lewis. I say I respect Mr. Lewis because he has the courage of his opinions, and because those opinions are manifestly the outcome of honest and thoroughly sincere conviction. Mr. Lewis was asked the crucial question of whether, supposing a child of his to be suffering from diphtheria, he would allow antitoxin to be used, to which he replied in the negative. "Would you," he was then asked, "let the child die?" to which he replied, "I would." Between those who hold his views and the generality of mankind there is an ethical abyss which it is impossible to bridge over. I fear that little or nothing can be done to influence this category of opinion. And now I come to the third category of critics—for I will not call them opponents—whose views are much more deserving of attention than either of those which I have so far mentioned. I allude to those who admit the necessity of experiments on living animals, but who urge the necessity of obviating by all possible means the infliction of pain. We are happily able to meet these critics on common ground. But, in dealing with this branch of the subject, the question at once arises of the extent to which pain is now inflicted. I do not say it is altogether absent, but I honestly believe it is reduced to a minimum. I quite admit that all reasonable safeguards against even occasional abuses should be instituted; and if the Commissioners, whose report we have for so long been anxiously expecting, can suggest any unobjectionable safeguards in addition to those which already exist, the public may feel assured that the scientific world will give to their proposals fair and even sympathetic consideration. But it is essential—I quote the words of the Royal Society, uttered through the mouth of their spokesman, Lord Rayleigh—that these safeguards "should be so framed as not unnecessarily to interfere with the advancement of knowledge." Unnecessary restrictions would, Lord Rayleigh added, "not only cripple or arrest the growth in this country of an important branch of biological science, but in so doing would reduce the efficiency of both physician and surgeon to mitigate or cure disease." Considering the eminence of the gentlemen who compose the Commission, I cannot doubt that full weight will be given to this essential condition. In any case, our duty as a society is clear. It is to welcome any well-considered and innocuous change in the existing law, but to offer a strenuous opposition to any measures which would retard the advance of knowledge, and which would result in displacing this country from the position it ought to occupy in the van of scientific and beneficent progress.

After delivering his address Lord CROMER put the question to the meeting that the report be adopted, and this was done unanimously by a show of hands.

Sir FRANK LASCELLES proposed a vote of thanks to Lord Cromer for presiding. After alluding to the debt which the society owed to Lord Cromer for all the help and guidance given by him to its affairs, Sir Frank Lascelles went on to speak of the recent meeting of the Royal Society for the Prevention of Cruelty to Animals when a resolution was passed adverse to Lord Cromer's vice-presidency of that society. Sir Frank Lascelles said that he was very glad that Lord Cromer had taken a line directed towards the maintenance of that society's interests, and had upheld the principle that there was no opposition between the objects of the Research Defence Society and the objects of the Society for the Prevention of Cruelty to Animals.

The vote of thanks was seconded by Dr. SANDWITH, who referred to his personal knowledge of Lord Cromer's administration in Egypt.

The vote of thanks was carried by acclamation.

Lord CROMER acknowledging the vote of thanks, referred to some of the early experiences of the Egyptian Society for the Prevention of Cruelty to Animals. With regard to the recent action at the meeting of the Royal Society for the Prevention of Cruelty to Animals, Lord Cromer said that he thought it would be a mistake to attach much importance to the "little skirmish" between himself and Mr. Coleridge. It was what his friend sitting near him, Sir Reginald Talbot, would describe as an affair of outposts. His only wish had been to save that society from the clutches of its more extreme supporters, and he hoped that his action had produced that effect. Lord Cromer went on to speak of the proposal that there should be more inspection under the Act. He said that the Research Defence Society would give thorough and careful consideration to such a proposal; but it was necessary to ask, What kind of inspection? The society could not support any proposal for any such inspection as might hinder or harass our men of science in their work. He went on to speak of the proposal that dogs should be exempted from experiments altogether. We are all of us, he said, fond of dogs. At the same time he believed that this proposal was founded on sentiment, not on reason. He did not see that it was in any way worse for a dog to die under an anæsthetic in a physiological laboratory than to die in the lethal chamber at Battersea. He hated cruelty in any shape or form; but he held that cruelty to a fox, or a cock pheasant, or a partridge, or a hare, was just as objectionable as cruelty to a dog. There were certain experiments, very limited in number, for which it was necessary that a dog should be used; and these experiments were of very great value to mankind.

The meeting then terminated.

THE CORONATION MEDICAL HONOURS.

WE printed last week the names of those members of the medical profession who were announced at the moment of our going to press as the recipients of titular distinction among the Coronation honours. The medical profession has received adequate treatment, and we feel certain that the list of medical honours meets with the warm approval of our readers. We now publish the complete list. Many of those who are thus honoured are so distinguished, and their claims to recognition in this way are so obvious, that it is scarcely necessary to mention their achievements or to detail the prominent positions which they hold and have held. Five baronetcies are conferred upon members of our profession.

Mr. Henry T. Butlin, the distinguished President of the Royal College of Surgeons of England, is also President of

the British Medical Association and consulting surgeon to St. Bartholomew's Hospital. His public services to medicine have been great and varied. He has been dean of the Faculty of Medicine in the University of London and President of the Pathological and Laryngological Societies, while he has held many other offices in the Royal College of Surgeons and at his old hospital.

Dr. William Osler, Regius professor of medicine in the University of Oxford, is famous throughout two continents. He has been professor of medicine at the Johns Hopkins University, and at McGill University, Montreal, and he has enriched the literature of medicine with many works of high scientific and literary value.

Dr. J. F. Goodhart, consulting physician to Guy's Hospital and the Evelina Hospital for Children, is an eminent clinician whose name is a household word in general medicine as well as pædiatrics.

Sir Charles B. Ball, the President of the Royal Academy of Medicine in Ireland, is a distinguished member of a distinguished family. He is the representative on the General Medical Council of the University of Dublin, in which body he is Regius professor of surgery. He is surgeon to Sir Patrick Dun's Hospital and honorary surgeon to the King in Ireland.

Sir W. Thornley Stoker, consulting surgeon to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin, is another eminent member of the Irish medical profession. He is a past-President of the Royal College of Surgeons and of the Royal Academy of Medicine in Ireland, and he is His Majesty's Inspector of Anatomy and Government Inspector under the Vivisection Act in that country.

Knighthoods have been bestowed upon Mr. A. A. Bowlby, C.M.G., surgeon to St. Bartholomew's Hospital and surgeon-in-ordinary to the King, who is a member of the Council of the Royal College of Surgeons of England, and served as senior surgeon in charge of the "Portland Hospital" in the South African war; upon Mr. R. Brayn, Home Office adviser in lunacy and late medical superintendent of Broadmoor Asylum; upon Dr. Alexander Dempsey, a well-known Belfast obstetric physician, who is physician and gynæcologist to the Mater Infirmorum Hospital; upon Dr. F. W. Hewitt, anæsthetist to the King and physician-anæsthetist to St. George's Hospital; upon the Hon. John McCall, Agent-General for Tasmania in London, and Member of the House of Assembly and of the Executive Council, who has done much useful public work and was President of the Central Board of Health; and upon Mr. F. C. Wallis, surgeon to Charing Cross Hospital.

The honour of K.C.B. has been conferred upon Inspector-General D. M. Shaw, who saw active service during the Crimea and the bombardment of Alexandria, and was in charge of several naval hospitals before his retirement; upon Inspector-General T. D. Gimlette, the head of the Royal Naval Hospital, Haslar; upon Surgeon-General W. L. Gubbins, C.B., Director-General of the Army Medical Service; upon Surgeon-General A. S. Reid, C.B., of the Indian Medical Service, lately principal medical officer of the Punjab Command; upon Major Ronald Ross, professor of tropical medicine in the University of Liverpool and the Liverpool School of Tropical Medicine, who was awarded the Nobel Prize for Medicine in 1902, and whose services in the campaign against malaria are world-famous; and upon Dr. B. A. Whitelegge, C.B., H.M. Chief Inspector of Factories and Workshops.

The distinction of K.C.M.G. has been conferred upon Dr. J. Rose Bradford, one of the two secretaries to the Royal Society, physician to University College Hospital, and among our foremost scientific physicians; and upon Dr. John Pringle, C.M.G., member of the Privy and Legislative Councils of Jamaica.

Dr. Bertrand Dawson, physician-extraordinary to the King and physician to the London Hospital, is appointed K.C.V.O.

The C.M.G. is conferred upon Dr. James W. Barrett, member of the council and lecturer of the University of Melbourne; Mr. Dugald Christie, head of the Mukden Medical Mission; and Dr. T. Zammit, Government Analyst, Malta. The following are appointed C.B.'s.: Inspector-General C. C. Godding, Inspector-General A. W. May, Inspector-General H. J. McC. Todd, and Fleet-Surgeon P. W. Bassett-Smith of the Royal Navy; Surgeon-General G. W. Robinson, principal medical officer of the Aldershot Command; Surgeon-General James G. MacNeece; Colonel C. F. Willis and Colonel T. Grainger, of the Indian Medical Service; Lieutenant-Colonel H. E. R. James, R.A.M.C. (retired), attached to the general staff at the War Office; Colonel G. S. Elliston, Administrative Medical Officer of the East Anglian Division; and Colonel P. B. Giles. Colonel J. R. Thomas, M.D., is appointed Honorary Physician, and Colonel Damer Harrisson, F.R.C.S. Edin., is appointed Honorary Surgeon to His Majesty for His Majesty's Territorial Force.

The C.V.O. has been conferred upon Fleet-Surgeon A. R. Bankart, Mr. Milsom Rees, and Mr. Mayo Robson, and the M.V.O. upon Mr. William Fairbank.

Dr. Michael Cox has been made an Irish Privy Councillor. The Hon. Sir Frederick Borden, Canadian Minister for Militia and Defence, has been made an Honorary Surgeon-General; and Sir James Reid, Bart., G.C.V.O., K.C.B., has been granted by His Majesty an augmentation of arms in consideration of services rendered to His late Majesty King Edward.

RECENT DEVELOPMENTS AT STRATHPEFFER SPA.

THERE are signs of a growing recognition that this country possesses health resorts offering natural facilities for the relief of disease which rival those presented at the well-known watering places abroad. A glance through our own columns for the past few years will disclose more than one example of a determined effort to make our home health resorts and their advantages better known to the public, and to bring them to a high level, not only in regard to treatment, but also to social attractions and domestic comforts. This is as it should be, and we are glad to recognise that the feeling is spreading that there is no reason why this country should be outstripped in this matter by foreign countries.

The British Isles possess every kind of natural mineral water which can be found elsewhere in the world. There are thermal waters, carbonated alkaline waters, saline purgative waters, brine baths, sulphur waters, iodo-waters, chalybeate waters, and so forth, the medicinal value of all of which in various ailments has been demonstrated in practice. The materials are plainly here, and if only a system of régime in regard to their medical application were adopted with the rigour and discipline commonly practised at continental health resorts a great stimulus would be given to the development of our home spas. It is a good omen that our railway authorities are beginning to see that the health resorts and spas upon the various lines can be made a source of revenue to their systems, and there is hope for the future of home balneological practice when our great railway organisations turn their attention seriously to the development of health stations along their routes. Fortunately, many of our lines bring within reach spots which are beautiful besides health-giving.

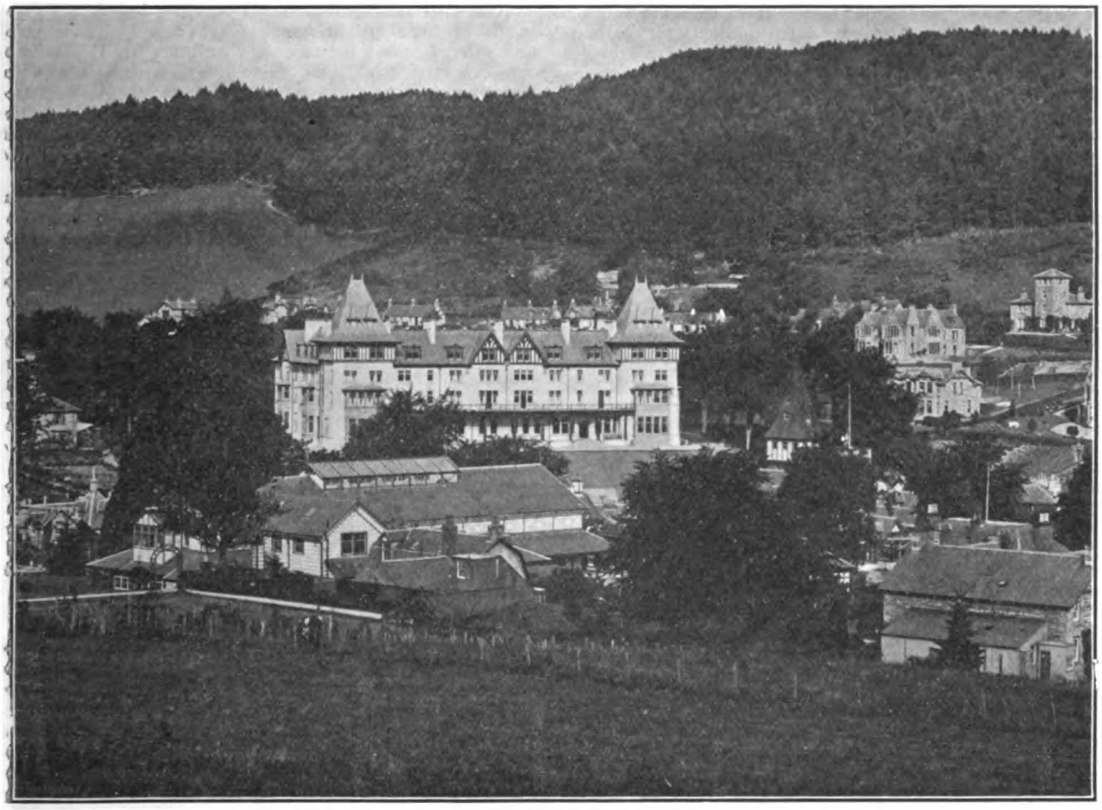
Nothing can exceed the beauty, for example, of the Highlands of Scotland, and these have long boasted a "spa" at Strathpeffer, which is situated in the very midst of some of the most romantic and picturesque scenery in North Britain. To the south-east approached from Perth is Aviemore, close by the Cairn Gorm mountains, then the gorgeous Killiecrankie pass, Kingussie, the heights of Dalwhinnie and Dalnaspidal. Mountain streams, lochs and glens form a continual panorama of great interest and beauty. To the west the Highland railway takes the traveller from Strathpeffer through country unsurpassed for the romance and magnificence of its scenery, until at length the sea is reached at the Kyle of Lochalsh, where the mountains of Skye and the islands of the Hebrides come in view to charm the eye and to impress the imagination with their wild grandeur. The enterprise of the railway in this part of the country has recently been manifested in its determination to provide Strathpeffer with a splendidly appointed hotel, a view of which is given in the accompanying illustration. The hotel is majestic in its proportions, and recalls the "hofs" of German health resorts. The justification for its existence is a sulphur spring, a health-giving environment, and a site endowed with great natural beauties.

The most important water at Strathpeffer is that drawn from the sulphur wells, of which there are three, but there

is also a chalybeate water of the type of the "Stahlbrunnen" on the continent. The strong sulphur water is quite redolent of sulphuretted hydrogen and contains in addition alkaline sulphides. Although strongly sulphuretted the water has a curiously cleansing effect upon the mouth owing to its antacid constituents. The reputation of Strathpeffer rests mainly upon successful results achieved in the treatment of chronic and subacute gout and rheumatism—especially the articular type—rheumatoid arthritis (in certain stages), and chronic rheumatism of muscles and nerves, such as lumbago and sciatica, but the waters have been used with benefit also in chronic skin diseases, disorders of digestion, urinary disorders, uterine troubles, and in functional nervous disorders.

The drinking of the waters, however, is only one form of administration; there is an admirable series of immersion baths, and peat baths and douche baths form a feature of the installation. Provision is made also for treatment by electric methods, by spray inhalations, and as auxiliaries may be mentioned the Nauheim bath and the Russian bath.

Apart from the abundant enjoyment afforded by the ever-varying landscape round Strathpeffer, the authorities at the spa have not been unmindful of the importance of providing recreation in other directions. There is an attractive golf course of 18 holes, situated at a level of 200 feet above the pump-room, which commands some delightful views of the valleys and hills of the surrounding country. Then there are bowling-greens, croquet-lawns, and a cricket-field, and a concert-hall in which during the season the orchestra discourses good music, while adjoining the hall are rooms for billiards, bagatelle, or card-playing, and a restaurant. The gardens are picturesquely laid out and well-stocked with flowers. There is a restful, peaceful air about the place which appeals especially to those who seek recuperation, and a respite from the wearing influences of worry and hustle.



Strathpeffer Spa, showing the new Highland Railway Hotel, Concert Room and Pump House.

The new hotel was opened on Tuesday, June 13th, a date which marks the opening of the Scottish Highlands season, and there were present at the joint invitation of the London and Northern-Western Railway Company, the Highland Railway Company, the North British Railway Company, and the Caledonian Railway Company, a large concourse of guests, including several medical men and representatives of the Scottish, provincial, and London press. The railway companies further extended a courteous invitation to a number of the latter gentlemen to a journey through the Western Highlands. The weather was ideal, and the trip through the magnificent scenery of mountain and loch was a source of veritable delight to all.

ASSOCIATION OF SCHOOL MEDICAL OFFICERS FOR SCOTLAND.—A general meeting of this association was held in Dunfermline on June 17th. At a business meeting Dr. Ernest T. Roberts, the President, was in the chair, 34 members were present, and 25 ladies and gentlemen were duly elected members of the association. A demonstration by students of the Physical Training College was given in the gymnasium. In the afternoon, through the courtesy of Dr. L. Cruikshank, chief medical officer Carnegie Dunfermline Trust, the members were enabled to visit the school clinic, the dental clinic, the baths, and the gymnasium, the various items of interest in these institutions being exhibited, and explained by the members of the staff. Dr. Cruikshank read a valuable paper on the Function and Management of the School Clinic. After discussion on the paper Dr. Roberts proposed a vote of thanks to Dr. Cruikshank for his paper and the trouble he had taken in arranging such an interesting and instructive programme, also thanking Dr. Ross, the chairman of the Carnegie Dunfermline Trust, for the hospitality extended to the members of the association. By the kindness of the Carnegie Dunfermline Trust the members of the association were entertained to lunch, and later to tea in the Pittencrieff Park.

MEDICINE IN SCANDINAVIA.

No. I.—NORWAY.

HUNDREDS of English medical men are acquainted with Norway as a land of holiday making, fishing, and shooting; but few have the time or opportunity to study the conditions under which their fellow practitioners in Norway live, and a short sketch of these conditions by one who has lived for many years in the country may not be without interest.

Medical Education in Norway.

The University of Christiania is the only educational centre which gives a medical training and degree. Here the would-be medical student must first pass the examination "Artium" before he can be registered as a student. This examination, which includes such general subjects as languages and mathematics, is usually taken at the age of 18 or 19. Having satisfied the examiners, the student commences the study of medicine, the average time taken to qualify being seven years. Three examinations are held. The first, which is commonly taken after three years' study, includes human anatomy and physiology, chemistry, botany, and zoology. This examination passed, the student begins hospital practice, and subsequently enters for the second examination, which includes pharmacology and toxicology, pathology and therapeutics, surgery, and the special diseases of the eye and the skin. The third examination, which is usually taken six months or a year later, includes clinical pathology and therapeutics, as well as surgical anatomy, gynæcology, obstetrics, hygiene, and medical jurisprudence. A curious regulation condemns the candidate who fails in the second part to enter for the first part *de novo*. Still worse is the fate of the unsuccessful candidate for the third part, who must take both the previous parts again. In practice, however, the unfit are weeded out by the first part, while less than 1 per cent. of the candidates for the other two parts fail. A powerful check is further put on the candidate entering for his final examinations too early by the division of the successful candidates into two classes. The occupants of Class I. form about one-half of the successful candidates. The general public seldom knows to which of the above classes any medical man belongs, but this division affects the seniority of a candidate for Government and other appointments.

Most of the text-books used are German or Scandinavian, but Cushny's "Pharmacology" and Withington's "History of Medicine" are recommended to the student by the Board of Medical Study, and several other English works are well known in Norway. As all, or nearly all, Norwegian medical men read German fluently, and most read either English or French, the demand for Norwegian text-books is strictly limited. There are three excellent medical periodicals, of which the monthly journal, *Norsk Magazin for Laegevidenskaben*, under the able editorship of Dr. E. Wang and his predecessors, has undoubtedly become the most interesting of all the Scandinavian medical journals.

Cost of Medical Training.—Number of Medical Men.

The cost of medical training, as of other forms of education, falls rather on the tax- and rate-payer than on the student, who, if his home is in Christiania, has little to provide beyond books and instruments. The low cost of education has naturally increased competition, and many of the most successful medical men are the sons of peasants. In the "eighties" the number of medical students was out of all proportion to the demand, the limitation of which has much reduced the supply of late years. To Norwegians who cannot find elbow-room at home there are, fortunately, excellent opportunities in the United States, where their fellow countrymen are numerous and prosperous, and where their reputation for professional skill is deservedly high. The number of Norwegians practising in the United States is now 64. At home there are 1161 medical men, whose ratio to the general population is as 1 to 2007. Of these, 437 are settled in the seven chief towns. There are 38 ladies practising, who form 3 per cent. of the total number of medical practitioners. Few of these have risen to any great distinction in the profession.

Organisation of the Medical Profession.

The Norwegian Medical Association (Den Norske Laegeforening) was founded in 1886, when the need for organisation had become urgent owing to overcrowding in the profession and the subsequent tendency on the part of the public to cut down prices. To-day the membership has risen to 1076. The discipline exercised by the executive is autocratic, but just, and largely owing to the vigorous personality of its secretary, Dr. Hansson, the association has become a most powerful organisation.

The Association has a wide and varied range of activity. In the capacity of a medical agency it is a reliable medium for the transfer of practices and the provision of assistants. It has long been an efficient check on quackery and the sale of secret remedies, the laws directed against which are most stringent. Thus an unqualified practitioner who ventures to treat tuberculosis or other infectious diseases is liable to a fine or imprisonment; and the importation and sale of secret remedies are prohibited. Unfortunately, the law still has flaws through which the adroit quack may successfully drive a coach and four. An instance of this occurred recently, when the vendor of an electric belt was tried for infringing the above laws. His acquittal (on a technical point of law) has been boldly exploited in subsequent advertisements.

A minor revolution has lately occurred in the South of Norway, where a district council decided to appoint two medical officers, whose services (with certain reservations) were to be at the disposal of every ratepayer free of charge. The question was thoroughly discussed by the Association at its general meeting in 1909, and the principle involved was provisionally accepted, though the terms demanded by the Association were far more advantageous to its members than those offered by the district council. However, the Association's terms were ultimately accepted, and the two medical men already practising in the district were appointed as its communal medical officers. The system has hitherto worked satisfactorily, but it is doubtful whether the ratepayers will countenance this expensive change in the long run.

Insurance against sickness and accidents is already compulsory upon certain classes, and the Government proposes to introduce a general scheme of compulsory insurance for all the poorer classes. The medical profession is, therefore, confronted with numerous problems, the solution of which is anxiously awaited by all concerned.

Government Appointments.

At present the majority of Government appointments consist of "distriktslaege embeder," corresponding to a certain degree to the appointments of the medical officers of health in England. These, of which there are 155, are much sought after, as the salary ranges, according to the district and the age of the officer, from £83 to £161. Private practice is permitted and a pension of about £111 awaits, as a rule, the medical officer, whose widow also, under certain conditions, receives a small allowance. The principal duties of these medical officers are the treatment and notification of infectious diseases, public vaccination, the treatment of paupers, and the supervision of the insane.

Post-graduate Study.—Scientific Contributions.

Post-graduate study is encouraged by the Government, which provides instruction and facilities for country practitioners to attend special classes in the larger centres. The desire to keep abreast of the times in medical knowledge is most noticeable, even in the older generation of practitioners, and I have witnessed an operation for appendicitis successfully performed, and the appendix removed, by a medical man whose knowledge of operative abdominal surgery was acquired after the age of 60!

Norwegian contributions to the science of medicine include Armaur Hansen's discovery of the bacillus leprae. His brother, Claus Hansen, has distinguished himself by his work on tuberculosis, and the rapid fall in the tuberculosis death-rate is largely due to the present tuberculosis laws, for which he is mainly responsible. Axel Holst's work on scurvy and beri-beri and Haaland's work on cancer are already well known in this country.

GOLF: BRISTOL MEDICALS *v.* BATH MEDICALS.—A match between the Bristol Medical Golfing Society and the Bath medicals was played at Failand, Bristol, on June 14th, and an enjoyable contest ended in favour of the home team by 5¾ points to 3¼.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 9159 births and 3781 deaths were registered during the week ending June 17th. Based on the results of the recent Census, the estimated population of these 77 towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this estimate, which had declined in the nine preceding weeks from 15·9 to 12 2 per 1000, was again equal to 12·2 in the week under notice. During the first 11 weeks of the current quarter the annual rate in these towns averaged 14·3 per 1000; in London during the same period the mean annual death-rate did not exceed 13·6 per 1000. The annual recorded death-rates during the week in the 77 towns ranged from 3·0 in Handsworth, 4·3 in Hornsey, 5·4 in Burton-on-Trent, and 5·7 in Barrow-in-Furness, to 17·2 in Sunderland, 18·0 in Stoke-on-Trent, 19·0 in Stockton-on-Tees, and 19·1 in West Bromwich. The 3781 deaths from all causes in the 77 towns during the week only exceeded by 7 the low number returned in the previous week, and included 364 which were referred to the principal epidemic diseases, showing a further slight increase upon the numbers in the two preceding weeks. Of these 364 deaths, 124 resulted from measles, 88 from infantile diarrhœa, 69 from whooping-cough, 47 from diphtheria, 28 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual rate from these epidemic diseases in the 77 towns, which had been equal to 1·0 and 1·1 per 1000 in the two previous weeks, further rose to 1·2. The fatal cases of measles in the 77 towns, which had been 153, 119, and 125 in the three preceding weeks, were 124 in the week under notice; the highest annual death-rates from this disease recorded during the week in these towns were 1·9 per 1000 in Stockport, South Shields, and Newport (Mon.), and 2·2 in Smethwick. The deaths of infants under two years of age attributed to diarrhœa in these towns further rose to 88. The fatal cases of whooping-cough, which had been 76 and 81 in the two previous weeks, declined to 69, and were fewer than in any week since January last; they were proportionally most numerous in Newcastle-on-Tyne and Warrington. The deaths referred to diphtheria, which had been 26 and 37 in the two preceding weeks, further rose to 47; they included 17 in London and its suburban districts, 6 in Stoke-on-Trent, and 3 in Cardiff. The 28 fatal cases of scarlet fever also showed a considerable increase upon recent weekly numbers; 4 were recorded in Stoke-on-Trent, 3 each in London and Manchester, and 2 each in Liverpool, Southampton, and Hull. Of the 8 deaths referred to enteric fever, 2 occurred in Portsmouth and 2 in Devonport. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased in the nine preceding weeks from 982 to 1141, had further risen to 1207 at the end of the week under notice; 190 new cases of this disease were admitted to these hospitals during this week, against 185 and 152 in the two previous weeks. These hospitals also contained 825 cases of diphtheria, 480 of measles, 273 of whooping-cough, 30 of enteric fever, and 4 of small-pox on June 17th. The 975 deaths from all causes in London showed a further decline from the low numbers in recent weeks, and included 139 which were referred to diseases of the respiratory system, against 134 and 141 in the two preceding weeks; only 3 deaths were directly referred to influenza. The deaths attributed to different forms of violence in the 77 towns, which had been 177, 175, and 172 in the three preceding weeks, further declined to 162 in the week under notice, and 346 inquest cases were registered. The causes of 37, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death recorded during the week were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 51 other smaller towns; the 37 uncertified causes of death in the 77 towns during the week included 6 in Liverpool, 5 in Birmingham, and 4 both in Sunderland and in Gateshead.

In the 77 largest English towns 6830 births and 3487 deaths were registered during the week ending June 24th. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had declined in the ten preceding weeks from 16 8 to 12·2 per 1000, further fell to 11·3 in the week under notice. During the first 12 weeks of the second quarter of this year the annual death-rate in these towns averaged 14·0 per 1000; in London during the same period the mean annual death-rate did not exceed 13·4 per 1000. The recorded annual death-rates during last week in the 77 towns ranged from 5·1 in King's Norton, 5·5 in Hornsey, 5·7 in Tottenham, and 6·8 in Walsall; to 15·7 in Liverpool, 15·8 in Wigan, and 17·0 in Stockton-on-Tees. The 3487 deaths from all causes in the 77 towns last week showed a decline of 293 from the number in the previous week, probably caused in some measure to delay in registration owing to the Coronation celebration, and included 273 which were referred to the principal epidemic diseases, against 341 and 364 in the two preceding weeks. Of these 273 deaths, 86 resulted from infantile diarrhœa, 81 from measles, 63 from whooping-cough, 21 from diphtheria, 14 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases, which had been equal to 1·1 and 1·2 per 1000 in the two previous weeks, declined last week to 0·9. The fatal cases of measles in the 77 towns, which had been 119, 125, and 124 in the three preceding weeks, fell to 81 last week, and were fewer than in any previous week of this year; the highest annual death-rates from this disease recorded in these towns last week were 1·4 in South Shields and 1·9 in Great Yarmouth. The 86 deaths attributed to infantile diarrhœa, which had increased in the five preceding weeks from 52 to 88, were 86 last week, including 21 in London and its suburban districts, 12 in Liverpool, and 6 both in Manchester and in Birmingham. The fatal cases of whooping-cough, which had been 81 and 69 in the two previous weeks, were 63 last week, including 15 in London and its suburban districts, and 5 both in Liverpool and in Leeds. The 21 deaths referred to diphtheria were fewer by 26 than the number in the previous week; 7 occurred in London and its suburban districts, and 2 each in Liverpool and in Bradford. Six of the 14 fatal cases of scarlet fever (against 28 in the previous week) were of London residents. The 8 deaths referred to enteric fever corresponded with the number in the previous week, and included 3 in London and 2 in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased in the ten preceding weeks from 982 to 1207, had further risen to 1223 at the end of last week; 159 new cases of this disease were admitted to these hospitals during the week under notice, against 152 and 190 in the two previous weeks. These hospitals also contained 808 cases of diphtheria, 467 of measles, 284 of whooping-cough, 32 of enteric fever, and 4 of small-pox. The 921 deaths from all causes in London showed a further decline from the low numbers in recent weeks, and included 111 which were referred to diseases of the respiratory system, against 141 and 139 in the two preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had declined from 177 to 162 in the four preceding weeks, further fell to 136 last week; 279 inquest cases were registered. The causes of 27, or 0·8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in London and its suburban districts, in Sheffield, Leeds, Bristol, Bradford, Nottingham, Stoke-on-Trent, and in 45 other smaller towns; the 27 uncertified causes of death in the 77 towns last week included 6 in Liverpool, 3 in Birmingham, and 2 each in Bootle, Rochdale, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons (based on the recent Census enumeration), 908 births and 466 deaths were registered during the week ending June 17th. The annual rate of mortality in these towns, which had been equal to 17·7, 16·9, and 14·9 per 1000 in the three preceding weeks, further declined to 14·2 in the week under notice. During the first 11 weeks of the current quarter the annual rate in these towns averaged 17 3 per 1000

of the revised estimate of their population, and exceeded by 3·0 the revised mean rate during the same period in the 77 large English towns. The annual death-rate during the week under notice in the eight Scotch towns ranged from 11·5 and 13·5 in Aberdeen and Edinburgh, to 15·2 in Greenock, and 17·9 in Paisley. The 466 deaths during the week from all causes in the eight towns showed a further decrease of 23 from the numbers in recent weeks, and included 64 which were referred to the principal epidemic diseases, against 67 and 56 in the two previous weeks; of these 64 deaths, 27 resulted from whooping-cough, 15 from diarrhœa, 14 from measles, 5 from diphtheria, and 3 from scarlet fever, but not one either from small-pox or enteric fever. The mean annual death-rate from these epidemic diseases in the eight towns during the week was equal to 2·0 per 1000, exceeding by 0·8 the mean rate from the same diseases in the 77 English towns. The fatal cases of whooping-cough in the eight towns, which had been 43 and 32 in the two previous weeks, further declined to 27, of which 12 occurred in Glasgow, 5 in Edinburgh, 3 in Greenock, and 2 each in Dundee, Paisley, and Perth. The 15 deaths attributed to diarrhœa showed a marked increase upon recent weekly numbers, 12 being of infants under two years of age; they included 8 in Glasgow and 5 in Edinburgh. The 14 fatal cases of measles also exceeded the numbers in recent weeks; 10 occurred in Glasgow and 2 both in Edinburgh and in Leith. The 5 deaths from diphtheria included 2 in Glasgow and 2 in Perth; and a fatal case of scarlet fever was recorded in Glasgow, in Edinburgh, and in Paisley. The deaths referred to diseases of the respiratory system in the eight towns, which had been 78, 76, and 52 in the three preceding weeks, further declined to 49 in the week under notice, and were 7 below the number in the corresponding week of last year. Of the 466 deaths from all causes in the eight towns 161, or 35 per cent., were recorded in public institutions, and 13 were attributed to different forms of violence. The causes of 10, or 2·1 per cent., of the deaths in the eight towns during the week were not certified or not stated; in the 77 English towns during the week the proportion of uncertified causes of death did not exceed 1·0 per cent.

In the eight principal Scotch towns, with an estimated population of 1,710,291 persons, 825 births and 435 deaths were registered during the week ending June 24th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 17·7 to 14·2 per 1000, further fell to 13·3 in the week under notice. During the first 12 weeks of the past quarter the annual death-rate in these towns averaged 17·0 per 1000 of the revised estimate of their population, and exceeded by 3·0 the revised mean rate during the same period in the 77 large English towns. The annual death-rate during the week under notice in the eight Scotch towns ranged from 8·3 and 11·5 in Aberdeen and Edinburgh to 15·5 in Dundee and 22·2 in Greenock. The 435 deaths from all causes in the eight towns last week showed a further decrease of 31 from the decreasing numbers in recent weeks, and included 58 which were referred to the principal epidemic diseases, against 56 and 64 in the two previous weeks; of these 58 deaths, 25 resulted from whooping-cough, 16 from measles, 13 from infantile diarrhœa, 2 from scarlet fever, and 1 each from diphtheria and enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·8 per 1000, and exceeded by 0·9 the mean rate from the same diseases in the 77 English towns. The fatal cases of whooping-cough in the eight towns, which had been 43, 32, and 27 in the three preceding weeks, further declined to 25 last week, of which 14 occurred in Glasgow, 3 in Edinburgh, 3 in Paisley, and 2 in Greenock. The 16 deaths from measles showed a further increase upon recent weekly numbers, and included 12 in Glasgow and 3 in Edinburgh. The 13 deaths of infants under two years of age attributed to diarrhœa were fewer by 2 than the number in the previous week; 5 occurred in Glasgow, 3 in Dundee, and 2 both in Edinburgh and Paisley. One of the 2 fatal cases of scarlet fever and the death referred to enteric fever were recorded in Glasgow. The deaths referred to diseases of the respiratory system in the eight towns, which had declined in the four preceding weeks from 78 to 49, were 51 last week, and were 10 below the number in the corresponding week of last year. Of the 435 deaths from all causes in the eight towns, 137, or 31 per cent., were recorded in public institutions, and 18 were attributed to different forms of violence. The causes of 14, or 3·2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns during the week the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,149,495 persons (based on the numbers enumerated at the recent Census), 692 births and 350 deaths were registered during the week ending June 17th. The annual rate of mortality in these towns, which had been equal to 17·1 and 16·1 per 1000 in the two preceding weeks, further declined to 15·9 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these towns averaged 18·5 per 1000; the mean rate during the same period in the 77 English towns did not exceed 14·3, and in the eight principal Scotch towns 17·3 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 19·2 in Dublin (against 11·2 in London), 14·4 in Belfast, 15·0 in Cork, 10·2 in Londonderry, 12·2 in Limerick, and 17·1 in Waterford; and in the 16 smallest of these Irish towns the mean annual death-rate during the week did not exceed 13·6 per 1000. The 350 deaths from all causes in the 22 towns during the week showed a further decline of 4 from the numbers in recent weeks, and included 23 which were referred to the principal epidemic diseases, against 29 and 21 in the two previous weeks; these 23 deaths were equal to an annual rate of 1·0 per 1000, which was slightly lower than the mean rate from the same diseases in the 77 English towns. These 23 deaths from the principal epidemic diseases in the Irish towns during the week included 9 from diarrhœa, 8 from whooping-cough, 3 from diphtheria, 2 from measles, and 1 from scarlet fever, but not one from enteric fever or small-pox. The 9 deaths attributed to diarrhœa showed an increase of 2 upon the number in the previous week, all being of infants under two years of age; 4 were recorded in Dublin. The 8 fatal cases of whooping-cough showed an increase of 7 on the number in the previous week, and included 4 in Belfast and 3 in Dublin. A death from diphtheria was recorded in Dublin, in Dundalk, and in Ballymena. Both the fatal cases of measles occurred in Dublin, and that of scarlet fever in Belfast. The 64 deaths referred to diseases of the respiratory system in the 22 towns corresponded with the number in the previous week. Of the 350 deaths from all causes during the week, 114, or 33 per cent., were recorded in public institutions, and 11 were referred to different forms of violence. The causes of 12, or 3·4 per cent., of the deaths registered in the 22 towns during the week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 1·0 per cent. in the 77 largest English towns, and was equal to 2·1 per cent. in the eight principal Scotch towns.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons (based on the recent Census numbers) 577 births and 297 deaths were registered during the week ending June 24th. The annual rate of mortality in these towns, which had been equal to 17·1, 16·1, and 15·9 per 1000 in the three preceding weeks, further declined to 13·5 in the week under notice. During the first 12 weeks of the past quarter the annual death-rate in these towns averaged 18·1 per 1000; the mean rate during the same period in the 77 English towns did not exceed 14·0 per 1000, and in the eight principal Scotch towns 17·0 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 15·1 in Dublin (against 10·6 in London), 11·1 in Belfast, 19·7 in Cork, 8·9 in Londonderry, 6·8 in Limerick, and 7·6 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week was equal to 15·7 per 1000. The 297 deaths from all causes in the 22 towns last week showed a further decline of 53 from the numbers in recent weeks, and included 27 which were referred to the principal epidemic diseases, against 21 and 23 in the two previous weeks; the 27 deaths were equal to an annual rate of 1·2 per 1000, which exceeded by 0·3 the mean rate from the same diseases

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar General's weekly returns; these two columns are therefore omitted from the Table.

in the 77 English towns. These 27 deaths from the principal epidemic diseases in the Irish towns last week included 10 from infantile diarrhœa, 8 from measles, 5 from diphtheria, 2 from whooping-cough, and one each from enteric fever and scarlet fever, but not one from small-pox. The 10 deaths of infants under two years of age attributed to diarrhœa showed a slight further increase upon recent weekly numbers, and included 5 in Belfast and 4 in Dublin. The 8 fatal cases of measles exceeded the number in the previous week by 6, and were all recorded in Dublin. Of the 5 deaths from diphtheria, 3 occurred in Dublin and 1 each in Limerick and Queenstown. Both the fatal cases of whooping-cough and the death from enteric fever were recorded in Dublin. The 48 deaths referred to diseases of the respiratory system in the 22 towns last week showed a decline of 16 from the number in each of the two preceding weeks. Of the 297 deaths from all causes in the 22 towns last week, 106, or 36 per cent., were recorded in public institutions, and 7 were referred to different forms of violence. The causes of 12, or 4·0 per cent., of the deaths registered in the 22 towns during the week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·8 per cent. in the 77 largest English towns, and was equal to 3·2 per cent. in the eight principal Scotch towns.

VITAL STATISTICS OF LONDON DURING MAY, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·3 per 1000 of the population, estimated from the unrevised returns of the recent Census to be 4,522,628 persons in the middle of the year. In the three preceding months the rates were 4·4, 4·3, and 4·1 per 1000 respectively. The lowest rates last month were recorded in the Cities of London and Westminster, and in St. Marylebone, Hampstead, and Camberwell; and the highest rates in Holborn, Finsbury, Poplar, Southwark, Bermondsey, Greenwich, and Woolwich. Two cases of small-pox, both belonging to Poplar, were notified in each of the last two months. The prevalence of scarlet fever showed a slight increase compared with that in other recent months; this disease was proportionally most prevalent in Fulham, Chelsea, Poplar, Southwark, Bermondsey, Wandsworth, Greenwich, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 1224, 1012, and 1018 at the end of the three preceding months, had risen again to 1128 at the end of last month; the weekly admissions averaged 160, against 142, 124, and 127 in the three preceding months. Diphtheria was slightly more prevalent than in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Hammersmith, Holborn, Finsbury, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 801 diphtheria patients at the end of last month, against 902, 881, and 827 at the end of the three preceding months; the weekly admissions averaged 100, against 120, 107, and 97 in the three preceding months. The prevalence of enteric fever showed a decline from that recorded in any previous month this year; this disease was proportionally most prevalent last month in Kensington, St. Pancras, Holborn, Battersea, and Wandsworth. There were 35 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 41, 32, and 22 at the end of the three preceding months; the weekly admissions averaged 5 in each of the last two months. Erysipelas was proportionally most prevalent in Stoke Newington, Finsbury, Bethnal Green, Stepney, Poplar, Southwark, Deptford, and Greenwich. The 29 cases of puerperal fever notified during the month included 5 in Wandsworth, 4 in St. Pancras, 4 in Bethnal Green, 3 in Stepney, and 2 each in Poplar, Bermondsey, and Lambeth. The 8 cases notified as cerebro-spinal meningitis included 3 in Stepney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the five weeks ending June 3rd the deaths of 5483 London residents were registered, equal to a corrected annual rate of 13·2 per 1000, against 19·0, 17·3, and 16·7 in the three preceding months. The death-rates last month ranged from 10·3 in Wandsworth, 10·5 in Stoke Newington, 10·7 in Lewisham, 11·0 in Woolwich, 11·2 in Greenwich, and 11·5 in Paddington and in Hampstead, to 15·2 in Bethnal Green, 15·3 in Holborn, 15·4 in Bermondsey, 15·5 in Stepney, 15·6 in Hammersmith, 16·6 in Poplar, 18·4 in Shoreditch, and 18·8 in the City of London. The 5483 deaths from all causes included 206 from measles, 18 from scarlet fever, 42 from diphtheria, 136 from whooping-cough, 6 from enteric fever, and 78 (among children under two years of age) from diarrhœa and enteritis. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Hampstead, Holborn, Battersea, Greenwich, and Woolwich, and the highest rates in Hammersmith, Hackney, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The 206 deaths from measles were 41 below the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Hammersmith, Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. The 18 fatal cases of scarlet fever showed a decline of 29 from the corrected average number, and included 3 in Islington, 3 in Lambeth, 2 in St. Pancras, and 2 in Deptford. The 42 deaths from diphtheria were 8 below the corrected average number; this disease was proportionally most fatal in Hammersmith, St. Pancras, Bermondsey, and Wandsworth. The 136 deaths from whooping-cough were 49 fewer than the corrected average number; among the metropolitan boroughs the greatest proportional mortality from this disease was recorded in Paddington, Kensington, Hammersmith, the City of Westminster, Shoreditch, and Bermondsey. The 6 fatal cases of enteric fever were 3 below the average, and belonged respectively to Hackney, Stepney, Poplar, Lambeth, Wandsworth, and Deptford. The 78 deaths from diarrhœa and enteritis among children under two years of age included 7 in Shoreditch, 6 in Islington, 6 in Stepney, 5 in Southwark, 5 in Lambeth, and 5 in Wandsworth. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 24·2 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet Surgeons: J. W. W. Stanton to the *Vivid*, additional for the *Colossus*, and to the *Colossus*, on commissioning; and L. Kilroy to Plymouth Hospital.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Francis H. Treherne, from the Royal Army Medical Corps, to be Colonel, vice F. B. Maclear retired (dated June 13th, 1911).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel John Battersby, Half-pay List, is placed on retired pay (dated May 19th, 1911).

Lieutenant-Colonel James R. Forrest retires on retired pay (dated June 21st, 1911).

The undermentioned officers, from the Seconded List, are restored to the establishment:—Captain Geoffrey W. C. Hughes (dated June 16th, 1911). Lieutenant John S. Levan (dated May 26th, 1911).

The under-mentioned Majors to be Lieutenant-Colonels:—Frederick J. Morgan, vice F. J. Jencken, promoted (dated May 12th, 1911); William H. Horrocks, vice R. P. Bond retired (dated May 19th, 1911); Charles H. Hale, D.S.O., vice W. B. Thomson, retired (dated June 7th, 1911); Hugh C. Thurston, C.M.G., vice F. H. Treherne, C.M.G., promoted (dated June 13th, 1911).

Colonel R. I. D. Hackett has taken up duty as Principal Medical Officer of the Karachi Brigade, Southern Army, India. Brevet-Colonel R. S. F. Henderson, K.H.S., secretary to the Principal Medical Officer, His Majesty

Forces in India, has arrived home on three months' leave of absence. Lieutenant-Colonel C. E. Faunce, from the Military Hospital at Gibraltar, has joined for duty at Chatham. Lieutenant-Colonel W. E. Berryman, on completion of a tour of service in India, has been appointed for duty at Woking. Lieutenant-Colonel J. F. M. Shine, at present serving in India, has been granted leave of absence home until Oct. 31st next. Lieutenant-Colonel G. E Hale, D.S.O., medical inspector of recruits in the Eastern Command, has taken over charge of the Station Hospital at Mhow. Lieutenant-Colonel R. G. Hanley, from the Dublin District, has arrived for a tour of service in South Africa. Major G. J. Stoney Archer has taken up duty as Specialist in Advanced Operative Surgery to the Burma Division. Major J. Girvin has been transferred from the Station Hospital at Deolali to Ahmednagar. Major T. H. J. C. Goodwin, D S O., from Quetta, has joined at Aden. Major H. G F. Stallard has been appointed to officiate as Secretary to the Principal Medical Officer, His Majesty's Forces in India, during the absence on leave of Brevet-Colonel R. S. F. Henderson, K.H.P. Major F. R. Buswell, who is serving in India, has been appointed to officiate as Principal Medical Officer of the Jubbulpore and Jhansi Brigades during the absence on leave of Colonel S. C. B. Robinson. Major M. P. C. Holt, D.S.O., surgical specialist Third (Lahore) Division, has been transferred from Ambala to Kasauli. Major G. S. Crawford, on return from duty at Malta, has been appointed to the Irish Command. M jor W. H S. Nickerson, V.C., from York, has been posted for duty to the Second (Rawalpindi) Division. Major C. W. R. Healey, at present serving in India, has been granted three months' leave of absence. Major F. Smith, D.S.O., sanitary officer of the Third (Lahore) Division, has been granted an extension of his Indian tour of service for one year by H.E. the Commander-in-Chief. Major E. C. Anderson has been transferred to the Fourth (Quetta) Division and appointed to command the Station Hospital at Karachi. Captain A. E. F. Hastings, from Allahabad cantonment, has joined for duty at Darjeeling. Captain R. A. Cunningham, from Agra, has been appointed Specialist in the Prevention of Disease to the Eighth (Lucknow) Division and placed in charge of the Brigade Research Laboratory at Allahabad. Captain A. Dawson has been selected to take charge of the Enteric Fever Convalescent Depôt at Wellington, Madras Presidency. Captain F. W. W. Dawson, from Dundalk, has joined at Dublin. Captain T. H. Gibbon, on return from a tour of service at Malta, has been appointed to Canterbury. Captain R. L. Argles has been granted one year's extension of his tour of service in India by H.E the Commander-in-Chief. Captain A. C. Duffey, from the Dublin District, has joined at Rawalpindi.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotion:—Captain to be Major: William Henry Dickinson (dated Jan. 28th, 1911).

The King has also approved of the retirement of Lieutenant-Colonel Lionel John Pisani (dated June 10th, 1911).

Colonel F. C. Reeves has arrived home on leave of absence from India. The services of Lieutenant-Colonel R. B. Roe, civil surgeon of Nagpur, have been placed at the disposal of H.E. the Commander-in-Chief of India by the Home Department. Lieutenant-Colonel J. M. Crawford, civil surgeon of Benares, has been appointed to hold medical charge of the Mirzapur District during the absence of Major W. S. Wilmore on deputation at the Central Research Institute, Kasauli. Lieutenant-Colonel J. T. Daly has been granted leave of absence home from India until Oct. 18th next. Lieutenant-Colonel H. Hendley has been temporarily reverted to military duty from civil employment. Lieutenant-Colonel A. W. Dawson has been granted leave of absence home for seven months. Major F. D. S. Fayrer has taken up duty as Agency Surgeon at Baghalkhand. Major A. Gwyther, civil surgeon at Saran, has been appointed to officiate as Civil Surgeon at Howrah. Captain J. Taylor has been appointed to officiate in charge of the King Institute, Madras, in succession to Captain J. Patton. Captain M. F. Reaney has been appointed for permanent duty under the Government of the Central Provinces. Captain G. McG. Miller has been granted six months' leave of absence home from India on the recommendation of a medical board. Captain W. W. Jeudwine, officiating civil surgeon attached to the Mayo Hospital at Lahore, has been appointed to officiate as Civil Surgeon at Mooltan in succession to Lieutenant-Colonel A. Coleman, transferred to Rawalpindi. Captain E. J. C. McDonald, district plague medical officer at Jhelum, has been transferred in the same capacity to the Gurgaon District. Captain W. M. Anderson has been appointed Civil Surgeon to Dehra Ismail Khan. Captain W. E. R. Williams and Captain H. P. Cook have arrived home on leave of absence from India. Captain A. E. Grisswood, district plague medical officer at Hoshiarpur, has been transferred in the same capacity to the Delhi District. Captain C. Holroyd has been selected for appointment to the Jail Department in the Bengal Presidency.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Philip S. Vickerman is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant-Colonel Albert R Henchley reverts at his own request to the rank of Major (dated June 16th, 1911). Major Albert R. Henchley resigns his commission (dated June 17th, 1911).

Attached to Units other than Medical Units.—**Major David R. Oswald resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated June 17th, 1911). Captain Thomas H. Thomson resigns his commission (dated June 17th, 1911).**

For Attachment to Units other than Medical Units.—**Robert Hill Shaw to be Lieutenant (dated May 20th, 1911). Robert Proudfoot to be Lieutenant (dated May 20th, 1911). Captain James Walker, from the 1st Lowland Field Ambulance, to be Captain (dated May 26th, 1911). Joseph Bernard Dawson to be Lieutenant (dated June 17th, 1911).**

THE TERRITORIAL DECORATION.

Royal Army Medical Corps.

The King has conferred the Territorial Decoration upon Major David Robert Oswald, Retired List.

DEATHS IN THE SERVICES.

Deputy-Surgeon-General Arthur Guy Elkington, late of the Brigade of Guards, on May 31st, at Appin, Farnborough Park, Hants, in his 79th year. He received his first commission in the Army Medical Service in 1853, and retired in 1887. He served in the Crimean campaign, 1854-5, and took part in the battles of Inkerman, where he was wounded, of Balaclava, and throughout the siege of Sevastopol (mentioned in despatches, British and Turkish medals, and the Medjidie of the Fifth Class).

Surgeon William Forrest Archibald, of the Royal Naval Hospital, Chatham, was drowned near Maidstone on June 23rd whilst boating with two brother officers. The deceased officer was appointed surgeon in 1906.

THE CORONATION HONOURS.

A list of the honours bestowed upon members of the medical profession will be found in another column, page 33. We congratulate in the name of the profession the large proportion of members of the services who find a place in that list.

THE ORDER OF ST. JOHN OF JERUSALEM.

The Duke of Connaught, Grand Prior of the Order of St. John of Jerusalem, will inspect the Corps and Divisions of No. 1 District ("the Prince of Wales's Corps"), St. John Ambulance Brigade, in Hyde Park on July 22nd. The General Assembly of the Order of St. John of Jerusalem will be held at St. John's Gate, Clerkenwell, on July 6th. The annual commemoration service will take place at 2.15 P.M. on the same day.

The King has given His Majesty's Royal licence and authority to Major Frederick Fitzgerald Carroll, R A.M.C., to accept and wear the Fourth Class of the Imperial Ottoman Order of the Osmanieh, which has been conferred on him by His Highness the Khedive of Egypt.

PURE CIDER.—At a meeting of the Devonshire Farmers' Union, held recently, the adulteration of cider came under discussion, and it was unanimously resolved to petition the Government to include cider in the new Food and Drugs Bill, and to prohibit the sale of any drink under the name of cider which did not contain 90 per cent. of apple juice.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—In his letter on the National Insurance Bill Sir Alfred Pearce Gould rightly insists on attention to "the underlying principles involved." But in expressing the opinion (tentatively endorsed in your leading article in the last issue of THE LANCET) that the profession ought to say, "We will have nothing whatever to do with contract practice or *per capita* payments," he seems to me not only to make the unwarranted assumption that the evils of contract practice are inherent to the system, but also to ignore the main object of Part I. of the Bill, which is "to provide for *insurance* against loss of health and for the prevention and cure of sickness" for a large section of the "working population."

The principle of insurance implies the devolving of individual risks upon some body which, in accepting them in large numbers at a fixed rate, guards itself against loss by the operation of the laws of average. It is no doubt possible that with regard to "medical benefit" the State might be that body, charging insured persons a periodical premium, paying medical practitioners by fixed fees according to the amount of work done by them in each case, and taking the risk of loss. But such a scheme would be unsound. Payment per visit, by a third party, would inevitably tend to extravagance, as there would be no inducement either to patient or to attendant to prevent doctoring from becoming excessive—a luxury as well as a necessity. No system of artificial control could be trusted to prevent the loss which would then fall on the State. This difficulty is removed by the medical practitioner's contracting for his attendance. He then accepts the insurance risks, but is safeguarded from inadequate remuneration by receiving from the State, which collects the weekly contributions of employer and employed, an equitable sum *per capita*. The amount of that capitation fee (or insurance premium) is, as Dr. Carruthers points out, a matter for actuarial calculation, based on ascertainable statistics. The total remuneration should be on the average equal to or (to compensate him for bearing the risk) somewhat in excess of the fees which the medical practitioner would have received for the same work in private practice.

The advantages of such an arrangement, if made on fair and liberal lines, should be great to all concerned. The sick poor would obtain an efficient medical service, not at the expense of the medical profession, but by the help of the contributions of those whose good health exempts them from the need of medical benefit. Medical practitioners who chose to take this class of practice would receive, through the State, payment at least equal to their present experience with the same class of patients, and without the annoyance of collecting it. It would be to the immediate interest of the medical attendant to get his patients well as safely, quickly, and agreeably as possible. It would further be to his interest to prevent his insured clients from falling ill, and thus he would become an active power in preventive medicine. In private practice the prevention of disease tends to reduce the pay as well as the work of the medical practitioner. Under such a contract system its tendency would be to reduce his work only. In all this not only his patients but the public also would participate. Moreover, it would be as easy to adapt such a scheme to the limit of £160 a year as to that of £2 a week, but with the higher limit the capitation fee would, of course, work out higher.

"Payment for service rendered" is no doubt a just system, but, on the one hand, we must not forget that medical fees are only acknowledgments for what is often of quite inestimable value to the patient, and, on the other hand, we must recognise that under the contract system, just as in private practice, it is in reality the service rendered which is paid for. The Government Bill is at present so entirely unsatisfactory as regards its provisions for medical benefit that the only course open to the profession is to decline to serve under such conditions. Its amendment, so as to render it a satisfactory and valuable measure, should not, however, be beyond the powers of enlightened statesmanship, provided sufficient time is allowed for its full consideration. The well-being of the community is the prime consideration. If we loyally put that before any class interests the public will soon realise that its health and true interest depend very largely on an efficient medical service, and that efficiency and good workmanship cannot be secured on a national scale without just and even generous treatment of the medical profession by the State.

I am, Sir, yours faithfully,

Sheffield, June 26th, 1911. R. J. PYE-SMITH.

To the Editor of THE LANCET.

SIR,—Would you be good enough to publish the enclosed communication and abstract from a memorandum prepared some months ago after long consideration of the problem by a committee of general practitioners, it being considered opportune?

In the leading article in your issue for June 24th you urge the medical profession to consider at this crisis whether by the means of payment for services rendered a way to an honourable settlement of the difficulty between itself and the Government might be found. This committee is convinced that this proposal does give the means desired, and is pleased to note that the influence of your journal can be counted on for that purpose.

A detailed scheme embracing the principles contained in the accompanying memorandum will no doubt be placed before the profession shortly for its consideration. For the moment the medical profession is only concerned to see that nothing is left in the Bill when it becomes an Act to make the adoption of the principle of payment for services rendered impossible. I am, Sir, yours faithfully,

E. ROWLAND FOTHERGILL, Honorary Secretary.

Brighton, June 26th, 1911.

[ENCLOSURE.]

NATIONAL INSURANCE BILL.

We, the undersigned, desire to submit the following memorandum which contains our views with regard to the mode of remuneration of those members of the medical profession engaged in the domiciliary treatment of the beneficiaries under the scheme, and at the same time to add that the views therein expressed are those held in all parts of the United Kingdom by a very large and important portion of the medical profession, probably by a great deal more than half of the total number.

JOSEPH H. KEAY, M.D., M.A., Chairman of the committee.
E. ROWLAND FOTHERGILL, M.B., B.S., Honorary secretary to committee.

(1) THE RISKS OF THE INSURANCE.

The State, being the "Insurance Company," should be responsible for these; no endeavour being made to shift them on to the medical profession. Amongst the risks, the following can be enumerated:—

(*a*) The extra medical attendance required in the event of a long strike with the accompanying deterioration of the health of those on strike as well as of their families.

(*b*) The extra medical attendance required on the unemployed and those dependent on them, in consequence of the vicissitudes of fashion or trade over which the working classes have no control.

(*c*) The extra medical attendance required in consequence of an epidemic of infectious or contagious disease.

(*d*) The advancement of social legislation with its bearing on the health of the nation, necessitating increased duties being required of the medical profession.

(*e*) The increase in the cost of the necessary appliances and in modes of treatment available in general practice, in consequence of the advances made in medical and surgical knowledge.

(*f*) The present ignorance, through want of reliable information, as to what the actual cost of an efficient medical service under a complete Invalidity Scheme would be. This ignorance can only be met by means of years of practical experience.

(*g*) The ignorance, which of necessity must exist for some time, as to how legislation for invalidity insurance will affect previous legislation—e.g., Workmen's Compensation; Employer's Liability; Examination and Treatment of School Children; Medical Assistance under the Poor-law.

(2) PAYMENT FOR ATTENDANCE, WITH A MAXIMUM LIMIT OF LIABILITY TO THE STATE AND THE EMPLOYER.

The beneficiary being the person, who in the first instance required the attendance, it should be made to his interest while not depriving himself of necessary attendance to keep such attendance within reasonable limits. The doctor should also be prepared, by taking a limited amount of risk, to help the State to inaugurate a scheme which would have so many advantages while at the same time eliminating the many disadvantages attached to other proposals.

The proposal is that:—

(1) Every beneficiary should be entitled to claim attendance for isolated occasions on a fixed tariff.

(2) That arrangements should be made with the doctor of the beneficiary's own choice by which a periodical medical examination should be obtainable. This would be the means used for the prevention of disease.

(3) That the beneficiary should have an interest in keeping the attendance within reasonable limits; but such incentive not to become a deterrent from necessary attendance being requisitioned.

(3) MACHINERY FOR OBTAINING ATTENDANCE.

(*a*) Vouchers supplied to the beneficiaries on application to some authorised person.

(*b*) Vouchers to be issued for varying periods not exceeding four weeks, and to be valid for a single illness only.

(*c*) Items of attendance and charges to be entered on the back of the voucher, which is to be returned at the expiration of its validity.

(*d*) In cases of emergency the attendance to be given at once, and a voucher obtained at the earliest possible opportunity after the first attendance.

If it is thought necessary, apart from the foregoing system of vouchers, to provide safeguards against over-attendance on the part of the doctor, the following methods, which depend on different principles, are submitted for consideration:—

(*a*) Medical supervisors as in France, as also in England for vaccination (Government inspectors), and for Friendly Societies (sick visitors).

(*b*) For every attendance of the doctor a small deduction to be made from sick pay, and in the case of patients not drawing sick pay, a small increased contribution might be levied for a sufficient number of weeks.

(*c*) That if a beneficiary is receiving what seems to be excessive medical attendance, he be required to submit to a special medical examination and report.

(4) THE FOLLOWING ARE THE ADVANTAGES.

To the State:—

(1) The principle of payment for work done is the most equitable and satisfactory.

(2) It conduces to smoothness of working between doctor and patient.

(3) The cost to the State could be no more than under an *adequate* capitation grant.

(4) As all classes of doctors would be willing to participate, the more efficient attendance guaranteed by this system will lessen the amount of sickness. It follows, therefore, that the cost of this method would be less in future years than under the capitation system.

(5) It will tend to increase the efficiency of the medical profession.

(6) The inclusion of women and children could be arranged without any further adjustment.

(7) Inclusion of chronic invalids, those engaged in hazardous employment, those ill through personal misconduct and the aged can be arranged for on this, the only satisfactory, basis.

To the medical practitioner:—

(1) He will be relieved of the onus of giving unlimited service for a limited premium.

(2) The trivial consultation and the unnecessary call will not be a continual source of annoyance.

(3) The remuneration will be in proportion to work done.

(4) There will be fewer unremunerative patients.

(5) The relation of patient and practitioner will be more cordial and personal.

(6) The freedom of the private practitioner will be retained.

(7) If additional duties should be required under the advance of social legislation or because of an epidemic, trade strike, unemployment, or any advance in medical or surgical knowledge, the necessary agreement between the State and the profession would need no further adjustment.

(8) The doctor in attendance on clubs would gain by increased fees more than he would lose by any transference of patients.

To the Patient:—

(1) He can command the advice of any practitioner at any time and at any place whether resident there permanently or temporarily.

(2) He can change his doctor, as in private practice.

(3) He is assured of receiving adequate attention.

(4) He has all the advantages of a private patient.

(5) His self-respect is maintained, as services rendered are paid for.

(6) He is made personally interested in the good health of those dependent upon him.

Alternative proposals have been placed before the medical profession. The committee would very briefly name some of the practical objections to each one. Most of the advantages of payment for attendance are impossible under either of the other proposals.

(5) WHOLE-TIME MEDICAL OFFICERS.

The practical objections to the success of this proposal are:—

(*a*) Those beneficiaries who up to the present have paid for a doctor of their own choice would resent being bound to engage certain doctors and would contract out; if public opinion even allowed such a scheme to become law.

(*b*) The institution of a bureaucratic doctor in the place of the family doctor would tend to officialism; and he, having duties placed on his shoulders of a gradually increasing amount, would lose sight of the primary object of his existence—the efficient treatment of those committed to his charge.

(*c*) It would be immaterial to the doctor how long the beneficiary remained on the sick list; and if he were urged to return the patient as soon as possible, there would often follow great injustice to the deserving and honest sick.

(*d*) The doctor would claim the right to a participation in the superannuation scheme, with a resulting great increase of liability on behalf of the State.

(*e*) The more experienced, independent doctor would decline to enter the service or would leave it as soon as possible, and thus the State would become dependent on a doctor of limited experience.

(*f*) Being forced to accept the services of a doctor not of their own choice, the beneficiaries would criticise him more severely, and be constantly complaining to the State Department.

(6) CAPITATION PAYMENT ON BEHALF OF A BENEFICIARY TO A DOCTOR SELECTED.

The practical objections to the success of this proposal are:—

(*a*) The more experienced independent doctor would decline to enter into any agreement with or on behalf of a beneficiary to take over the insurance risks rightly belonging to the State (see Section (1) above) or would cancel such agreement as soon as he was established, or farm the attendance out to a newly-qualified assistant and thus the State would become dependent on a doctor of limited experience.

(*b*) The doctor being paid a fixed sum would reduce the amount of his attendance to the least possible. As it is impossible for anyone except a doctor to define in a specific case what would be inefficient attendance, neither the beneficiary, the employer, nor the State would become aware of such beyond the information obtainable over a period of years as to the improvement or otherwise of the health of the nation as a whole. Under-attendance is a direct injury to the national health.

(*c*) The doctor would not be competent to give all the medical and surgical services required, and therefore the State would have to contract for these services on a higher scale. The original doctor, having a fixed payment, would transfer chronics, aged, those ill through misconduct, as well as exacting beneficiaries, as soon as possible to these specialists or to Hospitals, Infirmaries, Sanatoria, or other institutions, with a greatly increased cost to the State in consequence.

(*d*) Special arrangements would have to be made for attending those ill through misconduct, or who moved into another neighbourhood, whether at the time ill or in good health, or temporarily away on holiday. This could not be done on a capitation basis which would be equitable to the State, the doctor, and the beneficiary.

(*e*) There is no means to prevent vexatious calls being made on the services of a doctor; and if extra charges were allowed, there is no security for their payment.

(*f*) If a beneficiary became a chronic invalid or "aged" or ill through misconduct, the doctor would decline to renew the agreement on the old terms, and the State would thus be compelled to make other special arrangements.

(*g*) There is no incentive to a beneficiary to look after his own health or the health of those dependent on him, as he is secured against the cost of any consequent medical attendance.

(*h*) Those doctors who at present have some 6,000,000 of the proposed beneficiaries in sick clubs would have no incentive to transfer them into a State scheme, and would actively assist those persons and the Permanent Friendly Societies in making the scheme unworkable.

(*i*) The relative certainty of a steady income held out as an inducement to a doctor is only in fact a deferred payment of his earnings.

It is taken for granted that the State would be desirous to elaborate a medical service which in order to prove efficient would insure:—

(*a*) That prevention of disease and prompt and efficient attendance on the sick were always kept prominently in view.

(*b*) That there should be no coercion in dealing with several million persons who will become beneficiaries under the scheme, and who up to the present time have engaged privately a doctor of their own choice on terms mutually arranged. Any coercion would only lead to contracting out of the scheme and its consequent failure from a public health point of view.

(*c*) That the sick beneficiary would be returned to work with the least possible delay, the scheme therefore being approved of by employers of labour and the permanent benefit societies and other bodies giving sick pay whose active coöperation it would under such circumstances be likely to receive.

(*d*) That the beneficiary, whether at home or on a holiday, or on changing his address would be in benefit at all times and in all places (no matter what form of illness he had) and could at once requisition the services of a medical man if required.

In order to insure these four points it becomes necessary to secure the hearty coöperation of the whole of the medical profession.

The committee is of opinion that this coöperation can be secured only by adopting the principle of payment for services rendered.

To the Editor of THE LANCET.

SIR,—On the eve of the recent meeting of the delegates of the British Medical Association, not being a member I sent the following suggested resolution to the Secretary:—

That inasmuch as contract practice as at present carried on is degrading to the medical profession and injurious to the best interests of the public, the British Medical Association calls upon all practitioners holding friendly society or other club appointments to at once resign them; that a special levy, either compulsory or voluntary, be made on all members for the purpose of sustaining such practitioners in their action and indemnifying them against pecuniary losses; and that the coöperation of all other professional organisations be invited in carrying out the above recommendations.

This was a fighting resolution, and if it had been adopted the end of contract practice under Friendly Society control might have been within sight. Further, it would have strengthened Mr. Lloyd George's hands, for he would then have been able to say to the Friendly Societies, "You see, you have so badly treated the medical profession in the past that you are now without doctors, so that your only hope is to leave the matter in my hands and I will try to arrange an efficient medical service for you." Thus the battle would have been won, after one decisive action, and we would have been able to arrange our own terms.

But the army—horse, foot, and artillery—assembled on the banks of the Thames broke up camp, and now we are sniping. Being a political fighter all my life I could understand a fighting attitude on broad principles such as these, and Sir A. Pearce Gould in your columns justly lays stress on principles; but has not that chance gone never to return? (And parenthetically we may well ask if the British Medical Association feared that the holders of club practices would not toe the line?) Nevertheless, it behoves us now to take stock of our position. During 23 years' experience in cash practices in working-class districts in London, and never having there held any Friendly Society or club appointments, I have often observed how the medical men holding such appointments have gradually absorbed many of the private patients of their brother practitioners; and I can quite conceive if this went on long enough hundreds and thousands of such patients would have been added to the club lists of such practitioners without any protest on their part. And if the National Insurance Bill falls through no doubt these holders of Friendly Society appointments will continue to gain even a greater accession of club members in the future to the loss of private practitioners.

Next, let us suppose the Chancellor had given his colleague, Mr. John Burns, the first start in the series of social reform schemes anticipated, and that Mr. Burns had initiated legislation on the lines recommended in the Minority Report of the Royal Commission on Poor-law. How would men such as myself have fared? So far as I can see—and I called attention to the matter last year—a very large proportion of my patients would under the proposed sanitary service have been virtually pauperised, and many would have been taken out of my hands without the prospect of my receiving one penny compensation for them. I should instead have had to pay additional rates and taxes for their treatment. Under the National Insurance scheme, however, I am to receive a capitation fee for the greater number of these cases. We apparently all have short memories, but let us go back to last year only, when we shall find on the public platforms, associated with the authors of the Minority Report, many well-known members of the medical profession warm advocates of such legislation. In the columns of THE LANCET of July 23rd, 1910, p. 229, there was published from the pen of Mr. H. Beckett-Overy and another a strong appeal to the medical profession, urging the acceptance of those recommendations, so that legislative effects could at once be given to the Minority Report. At the time I wrote a letter, published in THE LANCET of Sept. 3rd, p. 760, protesting against what I held to be the exploitation of the profession advocated by the medical supporters of the Minority Report, but my recollection of the matter is that many of us would have been thrown to the wolves then without awakening any very great protest. And to-day what is our position? Nowhere in the United Kingdom can we shut our eyes to the precarious condition of the bulk

of general practitioners brought about by so many and diverse causes. Here, in the East End, as in other parts of London where I have practised, almost every person can go to hospitals and receive gratuitous treatment, and it is practically impossible to have any continuity in the treatment of cases amongst the working-class. In all fairness, then, I ask, What does the Bill offer us who are placed in this position?

So far as I can see it gives us payment for thousands of cases which at the present moment are receiving gratuitous treatment from one source or another, and for which we do not receive a penny. Personally, I think this is something to cause us reflection. Both political parties are pledged to an Insurance Bill and to Poor-law reform. Both schemes must come whoever is in power. On the main and vital points, almost unanimously put forward by the medical profession, we want simple justice and fair play. But I think as we are placed now it will be deplorable if instead of mending the National Insurance Bill we destroy it. The Chancellor has virtually given way on the point of free choice of doctors for the insured, and I have no doubt this point as well as others will be cleared up during the Committee Stage. I am sure then he would get over most of his other difficulties with us now, if he adopted, even as an alternative plan, the system of payment for work done as under the National Deposit Friendly Society with modifications for different localities and work. This would not make his scheme more costly and would go far to satisfy the profession. I have every hope that he will eventually be got to take this view and so assure the smoother passage of his measure. And having thus met us in a broad and statesmanlike spirit, if he would then turn his great financial genius to devise a contributory plan, based somewhat on Poor-law or Civil Service lines, to give the State insurance doctors a pension or superannuation allowance, thus laying the foundation of a future State medical service, he would, when heat has been dispelled, be considered by the bulk of general medical practitioners not "as a villain but as a hero."

I am, Sir, yours faithfully,

Mile End, E., June 19th, 1911. M. S. HARFORD.

To the Editor of THE LANCET.

SIR,—It may seem superfluous for anyone to write further letters on the vexed subject of the National Insurance Bill, but I do not think too many can be written on a subject which strikes so deeply at the financial side of medical life. We, as a profession, are so limited by etiquette in our lines of communication with the lay public that it is difficult for any of us to let the aforesaid lay public know our thoughts and feelings on this or any other important subject. We can do as I am doing, write to your valued columns; but how far do we reach by doing so?

I, personally, have no club patients, with one exception, the National Deposit Friendly Society. This club pays for work done, not at an exorbitant rate, but one at which one does not feel one is prostituting one's profession. You are, as I see in this week's issue, as a result of a letter from "A. K." of York, aware of the tariff used by this club. And I would ask the profession why, if any one club can pay on this basis, the State cannot do the same? In my opinion this club is the only one which gets honest work done for its members, because it is the only club which treats the labourer as worthy of his hire.

Anything more absurd and totally iniquitous than the Chancellor's suggestion it is difficult to imagine with a normal brain. As at present drawn it means that a man may earn £3 per week or slightly more, and in consideration of a payment of 1/40th of this weekly wage can get medical attendance for a year. One hates to think it, but what one is afraid of is that the men who have been willing to prostitute our profession for a capitation fee of 4*s.* per annum may be equally willing to degrade it by undertaking work on the at present totally inadequate suggested basis. I, personally, can see no other way of dealing with this question than that suggested by "F.R.C.S. Eng. in General Practice." Why cannot the General Medical Council pass a resolution to make it "infamous conduct in a professional respect." Were they to do so, no medical man who respects himself or his profession would resent it, and it were better if those outside this limit were dealt with by the Council, and drastically.

This Bill, which is calculated to ruin many a medical man, is so flagrantly unfair and predatory that it is not easy to speak or write calmly about it, but the one thing to be prayed for is that any existing professional jealousies shall be buried and an absolutely unanimous resistance offered to it, either voluntarily or, if that is too much to hope for, compulsorily. Why in the name of all that is fair and just should medical men be exploited for the benefit of the unfit and unthrifty? What other trade or profession would submit to such oppressive legislation? I know of none. Medical attendance is no more necessary than bread or meat or any other marketable commodity. If the labouring classes spent less in beer and tobacco no need would have arisen for any legislation of this kind. I have many patients whose wages do not exceed 30*s.* per week, and yet they are willing and able to pay a decent fee for work done. The cases who are not are in the majority of instances alcoholic or gamble, and therefore are either out of employment or absolutely unthrifty. Are we to put a premium on this class of being? It would appear to be so.

Apart from its medical aspect, the Bill is obviously ill considered. It suggests paying 7*s.* per week to any employee for a given period as compensation for unemployment, but it does not provide for the first week! Any man may be out of work for a week, and that is the time he most urgently needs help; but the longer he is out of work the more probable is it that he is to blame in some way, probably C_2H_5OH. It must be obvious that in its present form it puts a premium on loafing. Whereas if they paid him 10*s.* the first week and reduced it one or two shillings per week to zero, unless some special cause existed, it would tend to make the man look for work.

I am, Sir, yours faithfully,

June 19th, 1911. ERNEST STRATFORD, M.R.C.S. Eng., &c.

To the Editor of THE LANCET.

SIR,—The General Medical Council demands a certain standard of education, with a minimum number of years' (i.e., five years) study in preparation for the same. The cost of this is well known to our profession. We do not start medical practice with the object of being pure philanthropists, but of obtaining in return for our work just and reasonable remuneration. Will any sane person suggest that 1*d.* per week for highly skilled work is any remuneration at all? I think not. I believe there is no profession which in the past has done so much gratuitous work as the medical. Surely there is hardly a man who, if he has been any length of time in practice, has not repeatedly attended patients for all sorts of illnesses without payment, and has not asked for any, but when the State comes in and *orders* him to work for no remuneration at all it is surely time to say, *No*, and that very decidedly. This Bill practically abolishes all fees below 5*s.*, and one of its effects would be greatly to increase the competition for this fee, with the result that in order to obtain work some would be tempted to accept 3*s.* 6*d.* or less, so the damage would not only fall on those who lose the lower fees. No *per capita* payment that could be suggested would be any suitable payment at all.

Is it a fact that any man lives on club practice alone? Has not the club or similar work in the past brought with it private work, and has not this been the paying part? Have not the Universities and the licensing bodies power to refuse to allow their graduates and diplomates to accept absurd payment? Has not the General Medical Council power to make it "infamous conduct"? Under this Bill hundreds of medical men would be ruined—the sale of practices made impossible, the life of a doctor would be one of endless toil for no reward, bad work would multiply by leaps and bounds, for it would be impossible to give adequate time to the cases. There are many thousands of people who can well afford to pay 2*s.* 6*d.* or 3*s* 6*d.* fees who would have their treatment for nothing. The status of the profession would be lowered infinitely. We have but to be united, to resist in every way, and we *must* prevail. Our work is the highest and the noblest a man can do, and "the labourer is worthy of his hire." If there are any so poor (and we know there are some) that they cannot afford to pay small fees, let the State pay for them, but let us stand as one man—united, strong, resolute to have a just remuneration from those who *can* afford to pay. The suggestion of a limit of £2 or £3 a week is absurd; moreover, a distinction should be made between the married and the unmarried.

But let us not forget for a moment that the profession is passing through the gravest crisis in its history, and if once

any terms such as those suggested are accepted it may be impossible to alter matters, and the profession will be irretrievably ruined.

I am, Sir, yours faithfully,

REGINALD THORPE, M.R.C.S. Eng., L.R.C.P. Lond.

Elmbourne-road, S.W., June 21st, 1911.

To the Editor of THE LANCET.

SIR,—It does not seem to have been generally noticed that one of the "additional benefits" under the Insurance Bill is to be "medical treatment and attendance for any persons dependant upon the labour of a member." Schedule IV., Part II. (1). This as being one of the cheapest and most profitable benefits allowed will probably be largely claimed and will further diminish the remnant of private practice.

I am, Sir, yours faithfully,

F. MILTON, M.R.C.S.Eng., L.R.C.P. Lond.

Llanberis, June 18th, 1911.

To the Editor of THE LANCET.

SIR,—What the attitude of the medical profession should be towards the National Insurance Bill could not, I think, be put more clearly or with greater force than has been done by Sir Alfred Pearce Gould in his altogether admirable and well-reasoned letter to THE LANCET. It will appeal strongly, I think, to the large majority of medical men, who will feel much encouraged by his powerful influence and support. I have held Friendly Society appointments now for about a quarter of a century, and one great reason of our mistrust in them is, I think, that although they are well aware of the vastly improved conditions of the labouring and artizan classes, and of the higher rate of wages obtained in a large measure by the Trades Unions, they have not revised the rate of remuneration to their medical officers where it could possibly be avoided, or, if at all, only in a most grudging and inadequate manner. My "clubs" do not pay me on an average 5*s.* per head per annum, which is at the same rate my father before me held similar appointments. If a suggestion is made that the fees should be raised the reply has in effect always been, "Take it or leave it."

We well know that many of the members of the societies could as readily pay £1 per annum, or even more, as the ridiculous sum that we now have to accept for what is regarded as payment for our services. When we see these same members attending football matches, &c., in their thousands, often expending as much on a single outing as they offer their medical man for a year's services, we feel, indeed, that our present position with regard to them must be ended.

I am, Sir, yours faithfully,

June 19th, 1911. DUNELM.

To the Editor of THE LANCET.

SIR,—The National Insurance Bill has an aim with which we are all in sympathy, to help the workers while they are well, to provide savings to bear the cost of sickness, in order that, relieved in their illnesses from privation and anxiety, they may the more quickly return to work and become again useful to the State.

Mr. Lloyd George thinks the Bill will improve the public health and reduce sickness, and that the contributors will find so much more work done, and so much more return for their work, that they will never miss their contributions. Sanguine, but not impossible. What he has so far arranged is that every employed contributor—that is, roughly, every labourer or artisan (seamen, too, are included)—shall pay 4*d.* a week, his employer 3*d.*, and the State 2*d.*, or 39*s.* a year, to meet charges for doctors' fees (medical benefit), sanatorium benefit, sickness benefit (10*s.* or 5*s.* weekly for not more than six months), disablement benefit (5*s.* weekly), maternity benefit (30*s.*), and other benefits if the scheme is a success. The *Times*, I may say, fears the disablement benefit most, pointing out that in Germany it is only payable to a man who has been four years insured, but in our Bill it is to be payable after the second year; while, further, in Germany it is not given to a man if he is still able to earn one-third of his former wages, but here if he is "rendered unfit," and no precise statement of the degree of disablement is given. *Punch* has called this the "Sickness Ensuring Bill."

It is of special importance to the medical profession to know what is to be expended out of that 39*s.* in payment of medical benefit. That is nowhere stated. The approved societies and the Local Health Committees are to make arrangements with us "for insured persons to receive attendance and treatment to the satisfaction of the Insurance Commissioners." Mr. Lloyd George has talked of 6*s.* for us, but there is nothing but his speeches to guide the new Local Health Committees. Several people lately have said we should press to have nothing to do with the Friendly Societies, but to have everything arranged with the Local Health Committees. It is important, then, to understand who these committees are. They will cover the same area as a county or city council and will be in number from 11 to 22, of whom 6 will be appointed by the county council, probably from members of the local sanitary authorities, 6 will be insured members of the Friendly Societies, 6 will be insured deposit contributors (who will be explained later), 4 more will be appointed by the county council, of whom two will be doctors; statutory representation of women has been promised. No group here seems likely to be markedly friendly to the medical profession. Over one-half are the insured who are to get all their own benefits out of the 39*s.* after the medical benefit has been deducted. They can make what arrangements they like with the doctors, if the Insurance Commissioners approve, but they are more likely to give a capitation rate than to pay by fee, as payment by fee is uncertain in amount and cannot be so accurately forecast, and if they have become liable for a bill larger than their estimate it must go through the Insurance Commissioners to the Treasury and to the county council who, if they think the expenditure reasonable and proper, sanction it, and proceed forthwith, each of them, to raise half the quantity by taxation. It is quite easy to see how little anxious anyone will be to regard extra expenditure as reasonable, and what a wigging the Local Health Committee will get if its expenditure is in excess of its estimate; so there seems little doubt but that payment will be made on the capitation principle, which is easy to plan out and estimate exactly beforehand. As to the deposit contributors, they will not be members of Friendly Societies, probably because they are bad lives, and Mr. Lloyd George has said that 6*s.* would not cover their medical attendance, so he will see they pay more.

Mr. Lloyd George is anxious to make the sick comfortable, to put them in the way of getting well quickly; he says he cannot ask any more from the workmen, that the employer cannot give more, and that he has himself precipitated something in the nature of a constitutional revolution in his desire to raise the six millions already wanted for this Bill. The only thing left to squeeze is the medical profession. He has never discussed what we consider the vital points. At the meeting of representatives of the British Medical Association, when the wage-limit was suggested for discussion, he raised a prejudice against anyone who should venture to bring that matter up. We took clubs at 4*s.* in the hope that as we grew older, people of larger income than our present employers, men with £3 and £4 a week, seeing our assiduity and our success, might engage us to attend them and their families at higher fees. But now these men are compelled to insure, and we must attend them at the club rate, which few of them have heretofore demanded.

The Chancellor has now made a categorical answer to the communication addressed to him by the General Medical Council, and has declared his willingness to make one of the Insurance Commissioners a medical man. This, of course, is a move in the right direction, for without a medical Commissioner we may be certain that the recommendations of any Advisory Committee upon medical matters would run considerable risk of inattention. Otherwise there was nothing in the Chancellor's reply to the General Medical Council that was likely to reassure the medical profession, or to arrest that shortage of medical men, the probability of which has been conspicuously alluded to by the Council.

I am, Sir, yours faithfully,

June 19th, 1911. NAVITA.

To the Editor of THE LANCET.

SIR,—The second reading debate on this Bill has demanded serious consideration, and many persons regret that the procedure in the House precluded the opportunity for an immediate and a direct refutation of the many unsatisfactory statements by the Chancellor of the Exchequer. Most of us are in favour of the principle of the Bill. I myself am a Liberal in politics, and as a Liberal I contested a Parliamentary county division and a borough. I was in general practice for seven years and subsequently in consulting practice, and

for over 20 years was physician (and finally senior physician) to a large hospital for tuberculosis and diseases of the chest. Most carefully have I read the whole Bill, the memorandum, and nearly all the speeches on the second reading, and the statement by the Chancellor that "there is one part of the Bill that has escaped the attention of every doctor in the land" is incorrect.

Mr. Lloyd George stated that "the doctors proceed in their criticisms on five assumptions, all which are erroneous." I cannot say that none have done this, but all those with whom I have discussed the measure in private and at public meetings have most assuredly not done so. They and I have proceeded on the assumption that while some of the profession were opposed to the system of capitation payment, a capitation arrangement is the only workable method; but we suggested that, in the event of a capitation grant being ultimately decided upon, it should be laid down that, seeing that neither capitation nor amount is mentioned in the Bill, the *minimum* capitation fee for ordinary professional attendance (excluding surgical operations and bacteriological and kindred and allied work) be fixed and stated in black and white in the Bill itself at not less than 10*s.* 6*d.* per annum, thus leaving it open to increase the amount according to the necessities of particular localities. We have never assumed any attendance on families, but only on individuals. We have advocated some kind of selection by patients of their medical attendants (subject to the latter being willing to attend them) being arranged for, a point absent from the Bill. Mr. Lloyd George, when he was told that free choice of doctor was not mentioned in the Bill, quoted Sec. 14: "Every approved society and Local Health Committee shall for the purpose of administering medical benefit make arrangements with duly qualified medical practitioners for insured persons to receive attendance and treatment to the satisfaction of the Insurance Commissioners from such practitioners." This clause might protect medical men against Friendly Societies if the words "every approved society and" were omitted and the majority of each Local Health Committee and of the Insurance Commission consisted of medical practitioners, but not otherwise. Mr. Lloyd George said that "not a doctor in the country has seen that." Why, Sec. 14 (1) is one of the many points round which the doctors' objections have clustered! He added, "They (the doctors) are free to make any arrangements which they like, which the *societies* like, of which the Insurance Commissioners approve." Did Mr. Lloyd George think he was speaking to children? How can "they" *make* the "arrangements" which they *like* when the Bill, so far, *provides* for their forming only one-ninth, or at most two-ninths, of the Local Health Committee, one-third of which is to be appointed by the "approved societies"?

Mr. Lloyd George is seeking to confer advantages on certain classes at the expense of the medical profession, and the members of the profession are not going to submit to this. Mr. Lloyd George said, "There is absolutely nothing *prescribed* in the Bill which would preclude the doctors from making any of the arrangements which they themselves have been recommending during the past few days." True, nor is there anything "prescribed" in the Bill that will protect their interests in any way, and this is what we complain of, particularly as the members of clubs and benefit societies are, to a certain extent, picked lives, for they are medically examined prior to admission and admitted only if medically fit, while the "Post Office" crowd that this Bill would let in might be all diseased at the moment of admission—the Bill says nothing to the contrary.

Later on Mr. Lloyd George clearly showed what his idea of the profession is. He admitted that he had to take some basis for medical attendance. He said, "I took the basis of 6*s.* because I understood from the report (British Medical Association, 1903) that this was the sum which was better than most doctors ever expected—better than most of them asked for—and I thought at any rate I would be on the right side if I put the amount at 6*s.*" What satisfied a group of club doctors whose private practices were left untouched does not necessarily now satisfy a whole profession whose complete private practices are threatened with ruin by compulsory insurance. If Mr. Lloyd George's speech, from which I have quoted, is to be taken as representing his scheme, the medical profession should simply reply, "It is a hollow and ridiculous sham," and without the coöperation of the medical profession the sham is doomed. The voice of the medical profession as a body calls for a basis not lower than 10*s.* 6*d.* per head—if there is a capitation payment—and this, too, for only ordinary medical treatment; for a free choice of doctors by patients if the doctors are willing to attend them; perfect independence of all so-called friendly societies; a strong medical proportion on all committees, boards, and on the commission; and all these points to be stated clearly in the Bill itself (and not to be left over "for consideration between next August and April," as Mr. Lloyd George asks—i.e., after the Bill has passed), otherwise Mr. Lloyd George will have difficulty in finding his "*best* medical attendance." I enclose my card.

I am, Sir, yours faithfully,

M.D., D.P.H., M.R.C.P. LOND. (BARRISTER-AT-LAW).

June 17th, 1911.

THE POSITION OF THE PRESENT REFORM MOVEMENT IN ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—I am very glad to read Mr. H. Nelson Hardy's letter on the above subject in THE LANCET of June 17th, partly because the criticisms it contains are obviously the outcome of a thoughtful study of the subject, and partly because I can, I think, put such considerations before him as will help him to see the points he raises in a somewhat different light. His first point would seem to be that as there are far more anæsthetic fatalities under registered than under unregistered administrators—a fact that is, of course, incontestable—there would be very little gained by the passage of an Act which would only protect the public against the risks of anæsthesia conducted by the latter class of practitioners. The second point, I take it, is that the use of methylated in contradistinction to ethylated or ethyl-alcohol chloroform, introduces a grave risk into chloroform anæsthesia. May I be permitted to deal with these two points separately?

One of the chief contentions of those who have interested themselves in the present reform movement is that, considering the knowledge we now possess as to the physiological and clinical effects produced by anæsthetics, the public is not sufficiently safeguarded against the risks of these agents. It is maintained, in fact, that a large number of the deaths which annually take place during general anæsthesia are preventable. As one fatality after another is chronicled Science seems to say to all whose ears are attuned to her utterances: "Provided anæsthetics are administered by persons whose general and professional education has been such as to entitle them to employ these powerful drugs, and provided also that such agents are administered according to those principles which recent experiment and clinical study have elaborated, the risks of artificially induced unconsciousness will be so slight that no one requiring surgical treatment need hesitate to incur them. But if ignorant and unqualified persons be permitted to take upon themselves these responsibilities, or if properly educated and qualified persons be permitted to use these drugs in such a way as to transgress the laws which are now known to be essential for safe anæsthetisation, painless surgery cannot possibly be practised without incurring grave risks from the necessary anæsthesia." Science bids us indeed put our house in order, and the sooner we begin to do so the better for the safety of the public and for the credit of our profession. The question is, Where shall we begin? Surely we must, in the first place, inspect the whole fabric from basement to attic, and decide whether any alterations of a structural nature are needed in order that the house, when completed, may conform to modern requirements. Should it be found that such structural changes are needed, surely we must start at the very foundations and work upwards. Let us not become the laughing-stock of posterity by repairing and improving the upper floors of our house before looking to these foundations. In other words, let us first see that all anæsthetics are placed in the hands of those who have been sufficiently educated to be entrusted with the responsibilities of anæsthesia; and when this has been accomplished by legal enactment let us direct our whole attention to improving the conditions under which anæsthetics are administered by registered practitioners. I freely admit that the most radical

alterations are necessary in the conditions under which anæsthesia is now conducted by those whose right to administer anæsthetics cannot be questioned. But let us deal with irregular practice first, and thus lay the foundation of a new and better order of things for the future.

The second point raised by Mr. Nelson Hardy is whether or not the use of *methylated* chloroform introduces a risk into chloroform anæsthesia which is absent when ethylated or ethylic alcohol chloroform is used. Mr. Nelson Hardy implies that this is the case, and in support of his thesis he mentions the fact brought to light some years ago that at a certain London hospital where methylated chloroform was used more anæsthetic fatalities had occurred in a certain number of years than at another hospital of about the same size where it was customary to use ethyl-alcohol chloroform. But if Mr. Nelson Hardy will go more carefully into the matter he will find that there was a far more important difference than this in the conditions under which anæsthetics were administered in these two institutions. In the one in which the larger number of accidents arose no special attention was paid to what may be termed the personal factor in anæsthetising—that is to say, anæsthetics were often entrusted to young and inexperienced administrators. In the other institution, however, in which accidents were far less frequent, anæsthesia was almost invariably conducted either by visiting or by resident anæsthetists. In order, however, that I may more completely dispose of the methylated chloroform bogey, let me add that this particular brand of chloroform is that which I have for some years past recommended for employment in hospitals with which I have been connected, and that at those hospitals at which it has been employed at my recommendation no cases have arisen in which this particular brand seemed in any way responsible for difficulties or accidents. Furthermore, with the object of being consistent and of making myself perfectly certain as to the safety and efficiency of Duncan and Flockhart red label methylated chloroform, I may say that I have myself used this chloroform for the last four years and without any of those results which Mr. Nelson Hardy and the believers in the danger of this brand regard as likely to arise.

I am, Sir, yours faithfully,

June 20th, 1911. FREDERIC HEWITT.

INQUEST FOLLOWING A CASE OF "HEALING" BY CHRISTIAN SCIENCE.

To the Editor of THE LANCET.

SIR,—Will you permit me to point out a mistake which has crept into your report of the inquest on Miss Nora Bohm, who died under Christian Science treatment? It is stated that the lady was living in a Christian Science "nursing home." As a matter of fact, there is no such thing as a Christian Science nursing home, and the house in which the patient was living was simply an ordinary house to which anyone could have gone. May I also say that the practitioner called in a doctor after the patient's death, as that is usual in the circumstances? No Christian Science practitioner imagines that a doctor could, or should, give a certificate when he is called in in this way.

I am, Sir, yours faithfully,

FREDERICK DIXON.

Surrey-street, Strand, W.C., June 24th, 1911.

THE ELECTION OF DR. J. A. MACDONALD AS A DIRECT REPRESENTATIVE.

To the Editor of THE LANCET.

SIR,—I wish to thank the medical practitioners of England and Wales for choosing me to be their Direct Representative on the General Medical Council at the recent election rendered necessary by the regretted death of Dr. McManus. Immediately after the result of the election was declared I was called upon to attend the session of the Council at which the National Insurance Bill was discussed, and the report upon certain of its medical aspects prepared, which drew from the Chancellor of the Exchequer the reply published in THE LANCET last week. The consideration of the Bill by the British Medical Association in the Representative meeting and the Special Committee has made such great inroads on time and energy that my friends will, I am sure, forgive the delay in returning my thanks; though tardily expressed, my gratitude is none the less sincere.

It shall always be my endeavour to justify the confidence my brother practitioners have shown by electing me to so responsible a position at this critical time.

I am, Sir, yours faithfully,

Taunton, June 26th, 1911. J. A. MACDONALD.

THE ADVERTISING OF PATENT MEDICINES.

To the Editor of THE LANCET.

SIR,—It may seem ungracious if, in thanking you for your kind notice of the motion I made in the recent General Assembly of the Church of Scotland regarding secret remedy advertisements in the monthly magazine of the Church, I venture to encroach upon your space. Will you allow me to correct a wrong impression which your paragraph in last week's issue is likely to leave upon your readers regarding the decision of the Supreme Court of our Church on the matter in question? The Assembly was practically unanimous in adopting a modification of my motion. The committee in charge of the magazine had referred in their report to objections urged against certain forms of advertisement, and had reported a marked loss of income due to their refusal to insert questionable notices. Desirous of making an end of a particular class of these advertisements, which still appear in the pages of the magazine, I moved as follows:—

> The General Assembly thank the Committee ..... for their care in regard to the selection of advertisements to be circulated in the magazine, and instruct them to carry their endeavours to that end yet further by excluding all advertisements of secret or patent remedies of a medical or quasi-medical description, in order that the disinterestedness and Christian character of the accredited organ of the Church may be above suspicion in that respect.

Although I am sorry to say that some voices were raised in defence of the *status quo* on financial grounds, by an overwhelming majority my motion, down to the words "*yet further*" was carried, the Assembly preferring to make its instruction more general than my proposal seemed to suggest, so as to include within its scope *other objectionable advertisements also*—e.g., of all sorts of *bogus bargains*.

Permit me to add that I value very highly your words of encouragement. I know you would not willingly do injustice either to the Church I represent or to the committee in charge of its magazine.

I am, Sir, yours faithfully,

June 23rd, 1911. WILLIAM A. CURTIS.

CHILDREN'S CONVALESCENT HOME, WESTON-SUPER-MARE.—The annual meeting of the subscribers of this institution, which is in connexion with the Royal Hospital for Children, Bristol, was recently held. The medical report stated that during 1910 the children admitted numbered 386. 359 patients had been discharged during the year, and of these 254 had "recovered," 79 had "much improved," 23 had "improved," and 3 showed no signs of improvement. The financial statement showed that subscriptions and donations had slightly diminished.

THE "CONGRESSO NAZIONALE D'IGIENE" AT TURIN.—This, the first of a series of Congresses to be held in future years at one or other of the great academic or industrial cities of Italy, will be inaugurated on Oct. 5th and will sit till the 8th of that month. The agenda paper is both interesting and opportune, prominent among the subjects to be dealt with being "Malaria," by Professor Negri of Pavia; "Industrial Hygiene," by Professor Bianchini of Bologna; "Disinfectants," by Professor Frassi of Parma; "The Hygiene of Schools," by Professor Bordoni-Uffreduzzi of Milan; "Mediterranean Fever," by Professor Neri; and articles of diet, such as "Sugar," by Professor Giacosa of Turin; "Milk," by Professor Volpino and Professor De Matteis of the same school; and "Drinking Water," by Professor Abba, Professor Volpino, and Professor Cler, also of Turin. Further information as to the Congress may be had on application to the President, Dr. Luigi Pagliani, professor of hygiene in the local university.

THE NATIONAL INSURANCE BILL:
POSITION IN IRELAND.

(FROM OUR OWN CORRESPONDENTS)

IRELAND has been well called the country of contradictory problems, where effect does not always obviously follow cause; in other words, the conditions that go to make what may be called the social organism are so complex that unless there is a thorough knowledge of the whole national and local circumstances it is absurd to attempt to connect cause and effect. This is being well illustrated at present by what is taking place in connexion with the Insurance Bill.

Meeting of Dublin Graduates.

A meeting of medical graduates of the University of Dublin was held at Trinity College on June 26th, when the Provost was in the chair, to consider the Insurance Bill as it would affect the medical profession in general and medical practice in Ireland in particular. Sir Charles Ball referred to the differences which exist between medical practice in Great Britain and that in Ireland; the Poor-law system, for instance, is quite distinct in the two countries. The seven points approved by the British Medical Association were considered in detail by the meeting. A resolution was passed condemning the medical clauses of the Insurance Bill as unnecessary and inapplicable to Ireland, and requesting the Chancellor of the Exchequer to cancel those clauses as far as Ireland is concerned, and to remodel the present system of Poor-law and hospital medical relief, so that it may apply to present conditions of labour and employment in Ireland. It was further resolved to appoint a committee to draft a statement for submission to Members of Parliament on the proposed resolutions. Among those who spoke were Dr. Henry Jellet, Dr. F. A. Winder, Mr. J. H. Campbell, M.P., and Dr. J. Esmond, M.P.

Action of the Roman Catholic Hierarchy.

At an important meeting of the Roman Catholic hierarchy held at Maynooth on June 20th a resolution was passed requesting the Chancellor of the Exchequer not to extend the Insurance Bill to Ireland, but to set aside the State contribution necessary for financing the scheme to the credit of Ireland, either for an insurance scheme to be specially devised for the needs of Ireland, or for some other purpose that may be deemed more beneficial to the general welfare of the population; and they call upon the Irish party to urge this policy in Parliament. They base their argument on the fact that while the Bill may do for England and Wales, of which 78 per cent. of the inhabitants are urban and only 22 per cent. rural, it does not suit a country like Ireland, of whose population only 28 per cent. are urban and 72 per cent. rural, and of whom only a mere fraction—either urban or rural—are wage earners, the immense majority being workers on their own account, such as farmers, shopkeepers, and others, who neither receive nor pay wages. Further, in their opinion the measure would increase unemployment. There can be little doubt, however, that among other things influencing the prelates is the well-known fact that the small farmers and their children who work on the land can always at present obtain gratuitous medical attendance and medicine through the widespread dispensary system, which has no parallel in either England or Scotland.

Views of the British Medical Association in Ireland.

The members of the South-Eastern Branch of the British Medical Association in Ireland, who met recently in Clonmel, have passed resolutions expressing satisfaction that the views expressed by the branch on the State Insurance scheme have been endorsed by the Roman Catholic bishops and by the General Council of the Irish County Councils. The resolutions also state that if the Bill "is forced on the country, seeing that it does not propose to fix the amount or condition of remuneration for medical attendance, but allows it to be settled afterwards between health committees, advisory committees, insurance companies, and medical men, similar powers of arrangement as to the admission or exclusion of voluntary classes and as to the terms on which they may obtain medical benefits under the Act in Ireland should be insisted on when the gross annual emoluments of such persons exceed £75 per annum; and that voluntary and all other contributors whose gross weekly earnings exceed £2 per week be excluded from the operation of the Act." They urge also that the part of Section 6, Clause 59, beginning with the words "and these officers," be deleted from the Bill, and call on the Parliamentary representatives of the south-eastern area to give effect to the views of the branch.

Proposed Amendments by the Irish Nationalist Party.

Some of the Irish Members of Parliament—especially those representing industrial towns—rather favour the Bill, having a natural reluctance to oppose a measure which is meant especially to assist the toilers. All Members of Parliament, however, in Ireland are probably agreed that the State contribution under the Bill must be obtained for Ireland. In these difficult circumstances, a committee of the Irish Nationalist Members, consisting of 14 of the ablest of their number, is sitting in Dublin working out a scheme specially devised to suit the country. This proposed addendum or amendment to Mr. Lloyd George's measure is still necessarily in a fluid state, but the details are common property in Dublin, where they are being criticised by the medical profession. It is understood that the Irish party will recommend for Ireland a much less extensive policy, with smaller contributions from both employer and employed, and that most of the work under such scheme, if it becomes law, will be given to the Poor-law medical officers. It is hoped that by some such offer as this the Poor-law officers may be detached from opposition, and may be willing to give their help to the working of the measure. In an interesting article in the *Scotsman* of June 24th it is pointed out that if Mr. Lloyd George accedes to what probably will be the Irish Nationalist demand, he will destroy the financial basis of his Bill, and he will at the same time make it more than ever objectionable to the Scottish agriculturist and farm-servant. It is also pointed out that even now Germany does not provide sickness insurance for the agricultural community.

The Irish College of Physicians Takes Action.

The Royal College of Physicians of Ireland has issued the following circular to its Members and Licentiates:—

Royal College of Physicians of Ireland,
6, Kildare-street, Dublin, June, 1911.

DEAR SIR,—The Royal College of Physicians of Ireland has had under careful consideration the terms of the National Insurance Bill now before Parliament. The College agrees with the following policy which has been extensively adopted by the profession:—

1. That the profession should be adequately represented on all boards and committees controlling or administering medical benefits.
2. That the Friendly Societies should not make the arrangements with medical practitioners for the attendance and treatment of insured persons, nor otherwise administer medical benefits.
3. That provision should be made for exclusion from medical and maternity benefits of persons whose average income from all sources exceeds £2 a week.
4. That adequate remuneration should be assured to medical men for their services.
5. That the patient should be allowed to select his own doctor from those available, but subject to the consent of the doctor selected.

The College does not ask for expressions of opinion on these points, but before taking such further active steps as may be deemed advisable in reference to the Bill, is desirous of obtaining information as to the effect which the scheme embodied in the Bill would have upon the income and standing of the Members and Licentiates of the College.

Replies are therefore invited to the following questions:—

1. What proportion of your patients would come under the compulsory insurance scheme of the Bill?
2. What percentage of your takings during the past two years has come from attendance on workers who would become insured?
3. Are any of your patients members of clubs, and if so, what proportion, if any, of your income do you suppose you would lose under this Bill?
4. What proportion of your gross receipts is spent upon drugs and dressings?

The College appeals to those Licentiates or Members whose practice will be especially affected by the Bill to answer the foregoing questions, addressing replies to the Registrar, Royal College of Physicians of Ireland, 6, Kildare-street, Dublin. All information will be regarded as absolutely confidential.

We are, dear Sir, yours faithfully,
(Signed) J. HAWTREY BENSON, M.D., President.
T. P. C. KIRKPATRICK, M.D., Registrar.

Summary.

On the whole, then, it must be said that the mass of opinion against the application of the Insurance Bill to Ireland is steadily increasing. Several county councils have declared the Bill in its present form unsuitable to Irish conditions, and have asked for a postponement for full consideration; the Roman Catholic hierarchy,—a body with great influence in the formation of public opinion in Ireland—has passed resolutions in similar strain; a meeting of graduates of Dublin University last

Monday passed a resolution condemning the clauses concerning medical and midwifery benefits in so far as they applied to Ireland; and the Irish Medical Association has circularised all medical men in Ireland, seeking their opinion on various suggested amendments, and asking whether members of the profession are prepared to refuse employment under the Bill if satisfactory changes are not made before it becomes law.

THE DISPOSAL OF REFUSE ON THE RIVIERA.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AS most of the readers of THE LANCET know, the greater part of the Riviera consists of a narrow ledge of land with the sea in front and high mountains behind. Here are situated numerous winter stations, because the mountains shelter this narrow ledge from the cold winds and reflect the heat of the sun that faces them. For these reasons the Riviera has often been compared to a Dutch oven. It faces south. The sun plays the part of the fire, and people sit under the shelter of the mountains to bake themselves in its genial warmth.

Rapid Growth of New Towns.

This topographical situation confers on a comparatively northern latitude climatic advantages that, as a rule, can be found only much farther south. As usual in all human affairs there are, however, accompanying disadvantages. The most obvious is the want of room. When, with the exception of Nice and a few minor places, there were but fishing villages along the Riviera this did not matter. To-day the most pretty places are developing into large towns, such as Beaulieu, Turbie, Eze, and Cap d'Aile. A few years ago each of these villages consisted of a mere cluster of small cottages, now they have huge hotels, containing several hundred beds, and many exquisite villas surrounded by gardens where semi-tropical vegetation flourishes. The picturesque carriage road from Nice to Monaco, though 10 miles in length, has houses on either side nearly the whole way. Instead of little villages dotted along the road there will soon be a town stretching from Nice to Mentone some 16 miles long, and varying in width from 100 yards or so to half a mile. The little villages, which have now become quite important communes, with a town hall, a mayor and municipal council, will have to amalgamate and constitute the district councils or boroughs of a huge winter metropolis. Already these communes cannot exist without interfering with each other. Formerly the manure, dirt, and refuse of every household were consumed advantageously as manure, and placed at the roots of the neighbouring vines and olive trees. Now sewage schemes are being discussed, and it is discovered that if the main sewer of one commune should pass through the land of another commune the spot which would serve as a convenient sewer outfall for one sanitary authority must result in spoiling the beach and bathing of a neighbouring and rival district.

Mentone Refuse Thrown into Ravines.

Taking one of the many problems which the rapid growth of population renders more and more acute, there is the question of dealing with household refuse. At Mentone this difficulty has not yet been settled. Though Mentone is one of the older Riviera resorts and has now more than 10,000 inhabitants, the authorities have not yet decided what to do with the domestic refuse. At present it is taken away in carts along the beautiful and interesting road to Sospel and there thrown down into ravines. Nothing is done to prevent the horrible smell that arises when this rubbish begins to ferment; and, of course, it becomes a breeding ground for flies and mosquitoes. Everyone acknowledges that this is an absolutely reprehensible procedure, but as yet remedies have only been discussed. The upshot, however, of these debates is that the authorities have decided, I believe, on the erection of a destructor. But there are rival projects, and delay has arisen due to the difficulty of deciding which of them is the best. The first project consists of the Horsfall system as applied at Leeds and also, close at hand, at Monaco. It is proposed to build the destructor on the side of a hill so that a road passing behind might easily reach the higher level whence the rubbish is thrown on to the top of the furnace. The second project employs two furnaces at different temperatures. The air is to be carried through hot clinkers to help in the combustion of the material that is damp and has newly arrived. This is the Humboldt system, a firm that has its headquarters at Cologne. The third project is that of the British firm, Messrs. Heenhan and Froude, who are building a destructor at Havre and have their system at work at Burslem and many other places. Though it is doubtless embarrassing to decide which of these methods is best suited to the local necessities of Mentone, still the matter brooks no further delay.

The Monaco Refuse Destructor.

In this, as in many other respects, the Principality of Monaco was the first to set a good example. As far back as the year 1898, and at a cost of £3400, a destructor was built by the seashore in the Fontvieille district. The Horsfall system, which is very popular in England, was adopted. All the products of combustion that arise from the fire and the drying of the rubbish as it glides down towards the furnace, pass round and under, and then into the fire. These products of combustion are thus exposed to the highest temperature and rendered innocuous. To attain a very high temperature no cold air is allowed to reach the fire; it must first pass round the outside of the furnace and acquire some warmth. An occasional jet of steam discharged on the fire stimulates the air currents and adds to the temperature, which often exceeds 900° C. Outside, but close to, the furnace there is a chamber through which the hot air passes before it reaches the chimney stack. Here are placed carcasses, bad meat, &c., that have to be destroyed. The heat in this chamber is sufficient completely to destroy a horse's carcass during the course of the night. The clinkers that are the outcome of the destruction of the rubbish are very useful at the present moment. To increase the too small area of the Principality a sea wall is in course of construction just by the side of the destructor. The clinkers are thrown into the water between the sea wall and the shore, and thus land will be redeemed from the sea and the Principality enlarged. As some 70 cubic metres of rubbish can be destroyed in a day there is a pretty good yield of clinkers to constitute the foundations of the new territory. During all these years the destructor has worked well, and no complaints have been made.

Nice Refuse and the Fertilisation of the River Banks.

Nice is not so completely hedged in by mountains as some of the Riviera cities. Behind the town there is the broad valley of the Paillon, which is convenient for the disposal of rubbish, but the proceeding becomes very inconvenient when the wind comes from that quarter. The Paillon, and also the Var, which is not far off, are rivers with very arid pebble-strewn land on both sides. Indeed, the banks are of stone rather than land. So difficult is it to grow anything here that farmers come to Nice from great distances and gladly carry away the town rubbish at their own cost so as to bury it in their poor and unproductive soil. Though the population of Nice may continue increasing for many years to come, there is enough land on the banks of the Var and the Paillon to utilise for yet another 100 years all the household refuse and rubbish Nice can produce. Some of the worthless land on the banks of the Var belongs to the town. If the farmers do not fetch all the refuse away, the town can increase the value of its own property by rendering it fertile with its own rubbish. Higher up the Var and the Paillon there is much land available that could thus be rendered valuable. Here, then, is an admirable source of municipal revenue and a means of providing work for the unemployed if the public rights are jealously guarded. But there is the danger that as soon as the land has been rendered valuable at the public cost it will be jobbed away for the private profit of individual speculators. Unfortunately it does not seem as if the authorities at Nice recognise the necessity of holding remunerative property so as to meet the ever-increasing cost of local government. Yet it would be easier to collect rents from fertile lands, created by the municipality on the banks of the Paillon and the Var, than to incur the unpopularity of increasing the taxation which already weighs too heavily on the inhabitants of Nice.

Cannes Refuse Purified by Burial.

The municipality of Cannes possesses a good deal of land in the as yet uninhabited portion of an outlying dis-

called La Bocca. This is a good two miles away from the centre of the town, though there are many villas much nearer. Here, in a vast and flat field, the iron pipes to be used as water conduits were brought to be lined both outside and inside with cement. Now that this cementing of the pipes is concluded the big field is utilised for the disposal of the household refuse. The process consists of digging a trench, 5 feet wide and 2 feet deep, in summer. In winter, and for fear of the water, due to rain, the trenches dug are 3 feet deep. These trenches are filled with the refuse and the earth is placed back on the refuse. This is left to stand for five years. By that time a natural process of purification has taken place, the earth can be dug up and the ground used again. When I visited this place a trench had been dug at one end in virgin soil. This was a very heavy clay soil, and at the other end the soil was quite light and consisted of earth that had covered refuse for five years. There was no unpleasant smell whatsoever.

The important point to be observed is that the rubbish is buried just as it arrives. There is no sifting. This could not be done without exposing the refuse to the sun for at least 24 hours, and by that time it would begin to ferment and to smell. About 45 cubic metres of refuse are collected every day in four large four-wheeled carts and 17 two-wheeled tip-carts. Fifteen cubic metres of this refuse are sold for agricultural purposes, and in winter especially this is unloaded into railway trucks to be conveyed for the most part to Antibes. Here it is used to force plants, and more especially in hot-houses for early strawberries. It forms a sort of foundation or basis, which is covered over with choice earth in which the strawberries are planted. There then remain 30 cartloads which the town buries in the manner already described. The field at La Bocca is hardly big enough, it measures 1200 metres square. It is close to the celebrated umbrella pines which can be seen near the sea-shore as the train approaches Cannes. This land is worth 2*s.* the square metre, and belongs to a private owner, who allows it to be used for this purpose, and for such purposes it should continue to be used, for though five years' burial destroys bad odours, it does not follow that the land is fit to be built upon. But the municipality has at its disposal another field on higher land, which is preferable, especially when it rains. After the rubbish has been buried for five years it is sold at 60 centimes (or 6*d.*) the cubic metre. From the sanitary point of view this is excellent, but the agriculturist who digs this earth up five years later views the matter from a different standpoint. The golf club bought a quantity of this rubbish when it had been converted into what was supposed to be fertile earth; but sufficient account was not taken of the fact that the rubbish had not been sorted before it was buried. The remnants of an iron bedstead, a varied collection of shattered gallipots, a perforated saucepan, some old lamps, and much broken glass are not good substitutes for manure. The golf club found the soil at 6*d.* the cubic metre cheap, but the cost of the labour for sifting it was very dear. The municipality sometimes does the sifting, but then it sells the soil resulting at 8 francs the cubic metre. Even at this high price it only reckons to make a profit of 1 franc 50 centimes, or 1*s.* 3*d.*, per cubic metre. In these circumstances it prefers to sell the earth unsifted and get 6*d.* for it without any trouble at all. When sold at 8 francs the municipality has to dig it up, sift, and deliver it to the purchaser. If it is sold at 6*d.* the purchaser does all the digging and sifting himself and carts the earth away. However, these are minor considerations; the great fact remains that the sifting process is postponed until such time as it can no longer occasion a nuisance.

Mechanical Sorting and Crushing.

There can be no doubt that it may become a matter of necessity to employ household refuse, but the destructor renders very great service where space is restricted and there is a large accumulation of dwellings. This is notably the case at Monaco, as there is no room remaining in the Principality for agriculture. Liebig once urged that no country was sufficiently rich to be able, after the lapse of a certain time, to purchase back the fertilising principles of its existence which it had wasted. These words are significant to-day, as the tendency is to drain when possible into the sea, large rivers, or lakes, without making any attempt to utilise the sewage. It is becoming more necessary not to lose the fertile principles contained in house refuse. At the same time this must not become, as it used to be, a pretext for accumulating great heaps of putrescible matter. Fortunately there have been of late various inventions by which household refuse may be mechanically sorted and the utilisable portions ground into an inodorous powder. The difficulty will be to obtain from the sale of the fertiliser thus produced a sufficient revenue to pay the cost of elaborate machinery. It is said, however, that this can be done, as shown by important experiments made in the outskirts of Paris. But Paris is far away from the Riviera, though perhaps in time the Parisian example will travel southwards. Thus, in the end mechanical sorting and crushing will perhaps replace the methods described for dealing with domestic refuse.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

National Insurance Bill.

ON June 14th representatives of 26 Midland hospitals met to discuss the effect of the Bill upon hospital finance. Mr. Neville Chamberlain, senior representative of the General Hospital, which convened the meeting, presided, and representatives were present from the other Birmingham hospitals, West Bromwich, Wolverhampton, Walsall, Dudley, Stafford, the Potteries, Coventry, Warwick, Leamington, Stratford-on-Avon, Rugby, Kidderminster, Redditch, Cheltenham, Derby, Buxton, and Nottingham. Mr. Chamberlain remarked that a large part of their income was derived from the Hospital Saturday Fund and from the direct subscriptions of employers and workpeople. If they had to pay a compulsory sum weekly for insurance it seemed obvious they would not subscribe to the hospitals as in the past. Provision was made in the Bill for assistance towards the establishment of sanatoriums, but medical men did not seem to be at all unanimous nowadays in believing that these sanatoriums were going to be great curative institutions, and he submitted that it was a rash experiment to spend so large a sum on what was a doubtful matter and at the same time to withhold subscriptions from voluntary hospitals, about the value of whose work there was no doubt. Mr. Howard Collins (house governor to the General Hospital) gave the results of inquiries which he had made with reference to the finances of 40 hospitals within 50 miles of Birmingham. Thirty-two had supplied information. From the income of the hospitals he had taken out the total amount subscribed by employers from their places of business and the workpeople's contributions to the Hospital Saturday Fund as being affected directly, and the Hospital Sunday Fund and general donations as being only half affected. For the Birmingham hospitals the total income directly affected was £29,443. The estimated amount from employers and employees was £14,231; from the Hospital Saturday Fund, £7790; the Hospital Sunday Fund, £3278; general donations, £2236; and various other contributions, £4300. The total estimated amount affected was £34,478 out of a total income of £72,729, a percentage of 47·4. Taking the whole of the 32 hospitals it was estimated that £100,702 would be affected out of a total of £194,169. This was a percentage of 51·86. In the Birmingham hospitals the following figures applied: General, 32·6; Queen's, 79 7; Homœopathic, 43; and General Dispensary, 52·8 In the district the amounts varied as follows: Nottingham General, 65 3; North Staffordshire Infirmary, 67; Wolverhampton General, 68; West Bromwich, 95·8; Walsall, 76; and Nuneaton, 77 7. The variation was largely due to the proportion received from the Hospital Saturday Fund. The following resolution was carried unanimously:—

That this meeting, while welcoming any legislation which by reasonable arrangement will benefit the sick poor, is of opinion that the National Insurance Bill, if passed in its present form, will so gravely affect their income as to necessitate the curtailing of the amount and efficiency of their work, including a serious reduction in the number of beds they can support, and therefore urges that the Bill be so amended as to provide against such loss of income, whilst preserving their independence and maintaining an alternative to the Poor-law infirmaries.

—On June 15th a large meeting of the members of the

Birmingham branch of the British Medical Association was held in the Midland Institute and presided over by Professor J. T. J. Morrison. The meeting was undoubtedly the largest ever held by the profession in Birmingham, the branch drawing its members from a large area extending over portions of Worcestershire, Warwickshire, and Staffordshire. The Bill was discussed by Professor Jordan Lloyd, Professor H. Gilbert Barling, Dr. Langley Brown, Dr. Thomas Wilson, Dr. Harold Mason (Leamington), Dr. Radcliffe, Dr. Orton (Coventry), and several others. The resolutions formulated by the British Medical Association were unanimously passed, and the meeting pledged itself "to support this programme and to decline to serve on any terms that have not been accepted by the British Medical Association."

Hospital Saturday Fund.

The thirty-ninth annual collection was made on Saturday, June 17th, 1366 contributors paying into the Fund on the first day no less than £15,862, as compared with 1212 contributors and £14,265 last year. The total was £1002 better than the record year of 1908. It is hoped that before the Fund is closed at least £21,000 will be obtained. Sir Hallewell Rogers, the President, in addressing the workers, said that his view was that the National Insurance Bill would not affect the Hospital Saturday Fund to anything like the extent that might be feared on first thoughts. The objects of the Fund were, firstly, to support the Birmingham Hospitals and nursing societies with substantial annual grants, and to this end they divided among them £10,000 a year. There was nothing in the Bill to affect that situation. The hospitals would be as vitally necessary as ever. The Children's Hospital and Women's Hospital especially met the needs of patients who were not provided for by the Bill. Secondly, the objects of the Fund were to provide and support convalescent homes. There was nothing in the Bill that touched those homes. Up to date 40,000 patients had been treated free at their convalescent homes, and in their own right, without any rate aid, or State aid, or capitation grant from employers. Was it likely that the workpeople would stop such beneficent work? A large proportion of the Hospital Saturday Fund subscribers were already members of friendly societies and were already paying even more than 4*d.* a week. These would not have anything more to pay, and those who had been in societies for a large number of years would have less to pay than they do now for the particular benefits received. They therefore would not withdraw their Hospital Saturday penny. Then the Bill made no provision for the wives and children, both of whom formed a large proportion of the patients at the hospitals and also at the convalescent homes. Again, in the case of subscribers who were not at present members of friendly societies and would now have to start paying 4*d.* per week, they were no worse off than some thousands who in the past had annually joined the ranks of friendly societies without a thought of stopping their Hospital Saturday subscriptions.

June 27th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The University of Manchester.

IT is of interest to learn that the site and buildings of the University of Manchester represent £600,000. It must be remembered what Manchester has done for its University, for it has never had one halfpenny of public money as building grant. To keep pace with the ever-growing demands of the times, within the last ten years—1900 to 1910—the University has spent £212,461 on buildings. The total number of students attending the University is 1691, and of these 378 (including 21 women students) belong to the Faculty of Medicine. Certain minor changes have been made in the ordinances for the L.D.S., and the following new ordinances, *inter alia*, have been approved for the degree of Master of Dental Surgery:—

1. No candidate will be admitted to the degree of Master in Dental Surgery unless he has previously received the degree of Bachelor in Dental Surgery in the University.

2 Candidates, before proceeding to the degree of M.D.S., shall produce evidence of having, subsequently to the conferment on them of the degree of B.D.S., been engaged for at least one year in attendance on the practice of a dental hospital or in scientific work such as is conducted in the medical departments of the University, or alternately of their having been engaged for at least two years in practice as a dental surgeon.

3. Candidates may elect either (i.) to present an original dissertation or (ii.) to undergo an examination.

Singular Case under the Workmen's Compensation Act.

A somewhat unusual case under the Workmen's Compensation Act was tried in the Salford county court on May 19th, when a miner claimed compensation from a colliery firm for injuries sustained in an explosion due to shot-firing in one of their pits. A shot-firer named Pollitt was present as a third party at the instance of the employers. The claimant's case was that he was requested by Pollitt on Dec. 27th last to couple up a cable in connexion with the shot-firing in the mine. As he was in the act of responding there was an explosion which resulted in injuries incapacitating him from work. The defence was that the claimant, in obeying Pollitt's request, was contravening a statutory regulation made for the protection of the lives of miners. It was the duty of the shot-firer—a specially authorised person—alone to do the coupling, and if any other person did it a consequent accident could not be said to arise out of and in the course of his employment. The judge said that in his opinion the act of the claimant was one that might have resulted in danger to the lives of everybody in the mine, and under the circumstances was very serious indeed. As he was doing the work specially restricted to another person it could not be held that the accident arose out of and in the course of his own employment, and therefore there must be an award in favour of the employers. Owing to the gravity of the act, too, the employers would be allowed costs.

The British Psychological Society.

This society held its annual meeting in the Medical School, Manchester, on June 24th. There was a good attendance of members and visitors. Professor Sherrington was in the chair, and amongst the communications was one by the President on a method of demonstrating Listing's Law. The apparatus is ingenious and brings the facts clearly to the view of the onlooker. It requires the use of a dark room. Mr. Henry J. Watt read a rather abstruse paper on a New Classification of Experiences and the need for a theory which must be completely psychical. Mr. Cyril Burt discoursed on the Experimental Investigations of Emotional Dispositions and the need for investigation by the application of experimental methods, and by tests, both qualitative and quantitative, based on such processes as (1) apperception of ambiguous figures—e.g., a figure representing a skull and it maybe the figure of a woman, and determining which of the two appears first to the observer, which is prepotent; (2) memory for pictures; (3) preference for pictures; and (4) associative reactions. The sex question is obviously one of profound interest in this connexion. Dr. T. Graham Brown gave an account of the Perception of Movement of the Environment, such as the seeming movement of a cabin of a rolling vessel even when the head and eyes are fixed in relation to its walls. Dr. Brown expressed the opinion that the seeming movement of the wall of the cabin is not due to slight involuntary movements of the head and eyes, but seems rather to lie in the fact that sensations from the muscles of the eyes and from the labyrinths and proprioceptive organs of the muscles and joints of the neck all take part in the integration of the perception of movement of an object seen by the eyes. The seeming movements of a ship's cabin under the condition specified may be explained as due to the determination of the perception of movement by the compounding of the sensation of the fixed retinal image and the sensations from the labyrinths which move in space with each roll of the ship.

The Meals of Necessitous School Children.

The Salford town council, at its last meeting in May again discussed the question whether necessitous school children should have two meals a day supplied or only one. All the eloquence of the advocates of the two meals a day system, supported by quotations from Ruskin, Rowntree, Charles Booth, and other writers on social problems, failed to convince the council, and the proposal was once more defeated. It was successfully contended that already the council's education committee was doing as much as is necessary in this regard.

Infant Mortality in Salford.

The infant mortality in the borough of Salford for the

quarter ending April 1st was 118 per 1000 and the general death-rate 14·7 per 1000. Of the total deaths in the past quarter no fewer than 23·7 per cent., or nearly one-quarter of the whole, occurred in public institutions.

June 27th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Guild of Undergraduates.

AT a recent meeting of the Court of the University certain ordinances for the regulation of a Guild of Undergraduates were introduced and sanctioned by unanimous vote. The guild has as its objects "The promotion of corporate feeling and mutual fellowship among undergraduates and students, as well as of recreation in common and the cultivation of common intellectual interests." The Vice-Chancellor, in moving the adoption of the ordinances, said that they went no further than to constitute their guild a constituent body of the University, with a right to representation at the Court. They provide that every undergraduate shall, *ipso facto*, be a member of the guild, subscribing a sum not exceeding half a guinea annually. Provision is also made for the admission of associate members, the election of a representative to the University Court, financial administration, and the making of by-laws.

Chemists and the National Insurance Bill.

The chemists of Bristol and the surrounding towns met recently at the Grand Hotel to discuss the proposed insurance legislation. There was a very large attendance, and resolutions were passed approving of the separation of prescribing from dispensing, and asking that the dispensing should be entrusted only to persons registered under the Pharmacy Act, that patients should have freedom of choice of chemist, that payment should be fixed by scale and not on a capitation basis, and that pharmacists should have representation on the Central Advisory Board and on the Local Health Committee. It was further resolved that every dispensary employed under the Act should be subject to the Pharmacy Acts, the Food and Drugs Act, the Weights and Measures Acts, and all other Acts affecting traders; and that no further facilities be granted to carry on public dispensaries. All these resolutions were carried unanimously.

A Memorial Window at the Bristol Royal Infirmary.

A window, representing St. Elizabeth in robes of purple and grey, symbolical of royalty and humility, ministering to the sick and poor, has been placed in the chapel of the Bristol Royal Infirmary. Mr. Arnold Robinson of Bristol is the designer and the cost was defrayed by gifts from past and present nurses, members of the honorary staff and the committee. It is dedicated to the memory of eight nurses who have within recent years died while in the service of the infirmary. The ceremony of dedication was performed on Saturday, June 3rd, by Archdeacon Robeson.

Red Cross Society.

The Bristol branch of the Red Cross Society is now in possession of headquarters of its own in a central position. The various uses to which it is proposed to put all the rooms were explained to the officers of the various detachments by the county director, Mr. J. S. Griffiths, at a meeting held at the new headquarters. The work of the branch is progressing steadily, and it is hoped that eight or a dozen thoroughly served detachments may be formed with a few in reserve.

Compulsory Notification of Tuberculosis in Bristol.

At the last meeting of the Bristol health committee it was decided to report to the city council upon the importance of the compulsory notification of tuberculosis. It was also stated at the meeting that a lady would be prepared to give about £1000 towards the initiation of a dispensary for cases of tuberculosis. After some discussion the subject was left for further investigation.

Herbert Lorraine Earle Wilks, L.R.C.P. Lond., M.R.C.S. Eng.

Mr. H. L. E. Wilks, honorary surgeon to the Salisbury General Infirmary, died at his residence, The Retreat, De Vaux Place, Salisbury, on June 4th, in his forty-fourth year. The deceased received his medical education at Guy's Hospital, and qualified as M.R.C.S. and L.R.C.P. in 1891. Shortly afterwards he was appointed house surgeon to the Salisbury Infirmary. Mr. Wilks held this appointment for several years, and on his resigning the post was elected honorary surgeon to the institution. He was also surgeon to the Salisbury and South Wilts Provident Dispensary. Mr. Wilks had an extensive practice in Salisbury and the district, where he was very popular, and great regret is felt there at his early death.

The Health of Gloucestershire School Children.

At the last meeting of the Gloucestershire education committee it was reported that during 1910 over 13,000 school children had been medically examined, and only 43 per cent. of them were classified as being in a normal condition of health, although a large proportion of the ailments were of a minor character.

New Water-supply for Instow (Devon).

On June 12th the new water-supply for Instow was formally inaugurated in the presence of a large gathering. For some 20 years there have been various discussions at different meetings of the Barnstaple rural district council in reference to the water-supply of Instow, and eventually an arrangement was made with the Barnstaple Water Company to supply the little town. The water is carried from Barnstaple by 8½ miles of mains. Instow, which is one of the pleasantest of North Devon watering places, is to be congratulated upon at last obtaining an efficient and excellent water-supply.

The Treatment of School Children's Teeth at Torquay.

The Torquay education committee has obtained the sanction of the Board of Education to a scheme for providing temporary dental treatment for school children of the ages of 6, 7, and 8 years. Mr. J. Glanville Turle and Mr. Ludlow Strangways have been appointed to perform these duties until August 4th. These gentlemen will attend the children on two mornings every week for three hours on each occasion. The estimated cost of the undertaking is £40.

The Penzance Board of Guardians.

At a meeting of the Penzance board of guardians held on June 8th, Mr. C. Branwell, who was the only candidate for the post, was appointed medical officer for the fifth district. As already stated in THE LANCET, Mr. Branwell, owing to the insufficiency of the salary, resigned this appointment some months ago. The guardians then increased the remuneration, and appointed another medical man, but the Local Government Board refused to sanction the appointment. Mr. Branwell is to be congratulated upon securing his old post at a more adequate remuneration, and in being well supported by the local members of the profession.

June 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

National Insurance Bill.

AT the annual meeting of the Edinburgh branch of the British Medical Association, held in Peebles on June 24th, Dr. William Russell presiding, an informal discussion took place on the National Insurance Bill. The questions mainly discussed referred to the £2 wage limit, which by many of the members was regarded as too high. One country parish was particularly quoted in which with a population of over 300 souls there were not more than five persons with an income of over £150 per annum. Another point discussed was the question of mileage. One speaker, who had worked this question out in his own practice, stated that travelling by his own motor-car cost him 6*d*. per mile, and quoted the case of a patient whom he had seen a few days before 15 miles away, or 30 miles including the return journey. He charged this patient 15*s*. per visit, which allowed nothing for either his time or his skill, his contention being that on the question of mileage alone the Bill was unworkable financially.

Royal Faculty of Physicians and Surgeons of Glasgow and the State Insurance Bill.

At a largely attended extraordinary meeting of the Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow resolutions on the subject of the National Insurance Bill have been adopted, and the President, Dr. D. N. Knox, was requested to forward them to the Chancellor of the Exchequer for his earnest consideration. The resolutions were:—

1. That (*a*) the Insurance Commission, (*b*) the Advisory Committee, and (*c*) every Local Health Committee should include an adequate representation of duly qualified medical practitioners.
2. That "medical benefit" and "maternity benefit" should be administered by the Local Health Committees and not by "approved societies."
3. That in respect of the administration of "medical benefit" and "maternity benefit" the arrangements with "duly qualified medical practitioners made by the Local Health Committees should be such as to admit of free choice on the part of the insured person of the medical practitioner to be employed, and that the medical practitioner should have the right of refusal, such refusal being a matter of appeal to the Local Health Committee."
4. That in respect of the grant of subscriptions and donations to hospitals and other charitable institutions contemplated in Clause 17 of the Bill, the governing conditions should be assimilated to those set forth in Clause 15 (1) with regard to the administration of "sanatorium benefit."
5. That in respect of the provision to be made for "the supply of proper and sufficient drugs and medicines" under Clause 14 (2), the supply of proper surgical dressings and appliances should be included; and further, that steps should be taken to insure that the drugs and medicines are of the standard required by the British Pharmacopœia, and that the dispensing of prescriptions is carried out by qualified persons.
6. That "medical benefit" should include provisions for consultations and for operations when these are necessary; further, that the Local Health Committees be empowered to determine the remuneration of duly registered medical practitioners for special services rendered.
7. That in the case of an insured woman it should be made clear that "sickness benefit" accrues in addition to "maternity benefit"; and further, that in cases attended by a midwife the local health committee be empowered to pay for the attendance of a medical practitioner should such attendance be called for by the midwife, in accordance with the rules governing her practice.
8. That in respect of the deposit contributor class, which will consist of members other than the picked lives of the Friendly Societies, increased remuneration should be paid to medical practitioners.
9. That provision should be made in the Bill for exclusion from medical and maternity benefits of persons whose average income from all sources exceeds £2 per week.

Aberdeen Medical Men and National Insurance.

Under the auspices of the Aberdeen branch of the British Medical Association a mass meeting of the members of the medical profession within the area of the branch—Aberdeen, Banff, Kincardine, Orkney, and Shetland was held in the Medico-Chirurgical Society's Hall on June 15th for the purpose of considering resolutions and amendments anent the National Insurance Bill. There was a large attendance. The President, Dr. John Gordon, spoke of the medical aspect of the Bill, and referred to its effect upon the profession. He noted the fact that children under the age of 16—in the present form of the Bill—would not participate in money benefit, but would participate in medical benefit. He also drew attention to the fact that the Bill contained no provision for the statutory representation of the medical profession on any of the three administrative bodies, appointed under the Bill—the Insurance Commission, the Advisory Committee, and the Local Health Committee. Dr. D. Lawson, Nordrach-on-Dee Sanatorium, who represented the branch at the meeting held in London last month, reported shortly of the interview which the meeting had with Mr. Lloyd George, and showed how unsatisfactory, from the point of view of the profession, the meeting was. A lengthy discussion ensued, the Bill being strongly criticised in many cases. Finally, the resolutions contained in the circular of the British Medical Association of June 3rd were put to the meeting and unanimously carried. At a meeting of the Aberdeen Medico-Chirurgical Society held on June 14th the same resolution was carried unanimously.

Montrose Asylum: Annual Meeting.

The annual meeting of Montrose Asylum was held on June 13th. The usual grant of £325 was made to the Royal Infirmary. Dr. W. Leggett, chief assistant at Sunnyside, was granted an increase in his salary from £200 to £250 per annum. Dr. M. A. Milne was appointed X ray operator and chloroformist at the infirmary, and Dr. M. Connon, Dr. J. A. S. Grant, and Dr. H. J. Hoile were appointed medical officers.

The late Dr. MacKenzie, Kingussie.

The funeral of the late Dr. MacKenzie, Kingussie, took place on June 14th at Kingussie churchyard, amidst manifestations of deep sorrow on the part of the townspeople and the general public. There was a large attendance of mourners, and shops and all places of business were closed during the funeral. The schools were closed from midday, and a number of the advanced pupils, in whose welfare the deceased had taken a warm interest, attended. At the monthly meeting of the town council it was unanimously agreed to that a minute of condolence be inserted in the burgh records, and an excerpt ordered to be sent to the late Dr. MacKenzie's family.

Morningfield Hospital, Aberdeen.

The annual general meeting of the managers and subscribers was held on June 13th. The balance sheet showed a total income of £1965 5*s.* 2*d.*, and an expenditure of £2321 16*s.* 9*d.*, and an extra expenditure of £44 18*s.* for repairs. A special grant of £150 was transferred to the reserve account. The average number of patients in the hospital throughout the year was 79. The committee regretted to report a deficiency of £356 11*s.* 7*d.* on the year's accounts, the more so as the deficiencies on the last seven years had amounted to £1532, and further, that except for legacies the deficiency would have been much greater. The average cost of each patient for last year was £25 6*s.* 7*d.* The ordinary income was sufficient to maintain only 50 patients. The report was approved.

Dundee Royal Infirmary: Annual Meeting.

The annual meeting of the Dundee Royal Infirmary was held on June 12th. Income amounted to £13,372 17*s.* 1*d.*, an increase of £82 over last year. The principal item of increase was in collections from mills, factories, and works, which exceeded last year by £267. The greater part of that amount arose from Mr. J. K. Caird having contributed sums equal in amount to the collections of his workers at Ashton works and Craigie works for the years 1909–10 and 1910–11, the former having been received too late for inclusion in last year's accounts. The ordinary expenditure amounted to £16,445 17*s.* 3*d.*, an increase of £385 17*s.* 6*d.* over last year. The extraordinary expenditure amounted to £1653 2*s.* 4*d.*, leaving a total deficit of £4726 2*s.* 6*d.* The chairman said the directors had agreed to the continuation for another year of their agreement with the directors of the Royal Asylum relating to the admission and treatment of certain nervous disorders. The Sidlaw Sanatorium had at present 13 adult patients and 28 children. The new out-patient department of the infirmary, to which Mr. Caird contributed a gift of £2400, was opened last month, and was found convenient for the work. The number of in-patients treated in the infirmary during the year was 4098, as against 4038 during the previous year. In the maternity department there had been 370 in-patients, an increase of 50 over the previous year. There were 20,230 out-patients as against last year's 19,516. Altogether there were 31,921 cases treated as against 32,340. The average cost per bed occupied was £55 2*s.* 1*d.*, which was a reduction of 13*s.* 8*d.* per bed over the previous year. Dealing with the Insurance Bill, the chairman said that apprehensions had been felt all over the country that the Bill, if passed into law in its present form, might strike a serious blow at the finances of their hospitals, which were largely maintained by voluntary subscriptions, inasmuch as employers and employed would alike be unwilling to continue their voluntary subscriptions when they were separately for the same purpose taxed by the law of the land. After reference to what has been done in the matter by the General Hospitals Association, he moved the adoption of the report, which was unanimously agreed to.

The Population of Aberdeen.

At a committee of the Aberdeen town council meeting on June 14th Professor Matthew Hay, medical officer of health, pointed out that the population of the city had increased 8 per cent., as compared with Glasgow 9 per cent., Edinburgh 4 per cent., and Dundee 2 per cent. If the population of Oldmill Poorhouse and Kingseat Asylum had been included in the population, the Census figures for the city would have been 165,184, as against Dundee 165,006.

Aberdeen University Anthropological Society.

A meeting of the Aberdeen University Anthropological

Society was held in the Anatomy Theatre, Marischal College, on June 16th, when a very interesting lecture was given by the Rev. F. G. Bowie on the inhabitants of the New Hebrides, where he has laboured for 15 years. Mr. Bowie described the various superstitious customs peculiar to the inhabitants, dealing particularly with their method of the treatment of disease, the problem of caste, and the relations existing between the inhabitants of various villages. The lecture was illustrated by a series of photographs and by numerous specimens.

June 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Visit of the King and Queen.

Two items in the programme of the forthcoming visit of Their Majesties to Ireland are of medical interest. Her Majesty the Queen has consented to visit the Coombe Lying-in Hospital and declare open the new dispensary buildings. The Collier Dispensary for the Prevention of Tuberculosis is to be opened by His Majesty the King with the Queen. Dr. J. T. Crowe, who has been medical superintendent of the Royal National Hospital for Consumption at Newcastle for some years, is to be medical officer of the dispensary, with Dr. Daniel as assistant, and Mr. W. Lombard Murphy as throat surgeon.

Meeting of the Irish Medical Association.

The annual meeting of the Irish Medical Association was held recently in Cork. The report showed that there were 425 paying members for 1910. During the year the Association, in conjunction with the Irish Committee of the British Medical Association, had taken steps to press forward the scheme for a National Medical Service. The main lines of the scheme approved are those of the Vice-Regal Commissioners' Report, with certain amendments. The main business at the meeting was, however, the discussion of the National Insurance Bill. The Association approved of the conference of delegates held on June 9th,[1] and appointed a committee, consisting of the President, Dr. Jeremiah Cotter, of Cork; the honorary secretary, Dr. A. G. Robb, of Belfast; Mr. G. U. Macnamara, of Corofin; and Dr. L. Kidd, to wait on Mr. Lloyd George and the Irish Members of Parliament. It is reported that the Chancellor of the Exchequer has left the whole matter of dealing with Irish medical men to the Irish Party, and that they are at present busily engaged in drafting a Bill, the main line being that the compulsory part is to be given over to the dispensary medical officers and the voluntary portion to be dropped. So far the party drafting this measure have not received any medical deputation. It will be interesting to see what sort of constructive Bill the hitherto most destructive critics in the House of Commons will produce. Subsequently a referendum of the whole profession in Ireland is to be procured and steps taken for the holding of a mass meeting in Dublin, at which, with the assistance of the increased information so obtained, all the medical practitioners of Ireland will have an opportunity of deciding what definite action should be adopted in what is regarded as a very grave crisis for the profession. The annual meeting was one of the largest held for many years, due, doubtless in great measure, to the interest taken in the Insurance Bill. The social functions organised by the local executive committee were a complete success. The President of the Association and Mrs. Cotter gave a luncheon to the members on the first day at St. Antony's Hall, and Professor B. C. A. Windle, President of University College, and Mrs. Windle provided afternoon tea. A large gathering attended the annual banquet at the Imperial Hotel the same night. Amongst the official guests present were the Lord Mayor of Cork, the Recorder of Cork, the City High Sheriff, and Mr. Maurice Healy, one of the Members of Parliament for the city. Whilst the medical men and their guests were dining, Mrs. Cotter provided a musical entertainment for the ladies in another part of the hotel. The following day the s.s. *America*, chartered by the local committee, conveyed a large number of the members and their ladies down the river to several of the beauty spots in the harbour, an excellent luncheon being provided. That night the Lord Mayor and Lady Mayoress held a conversazione in the City Hall. The following day the City High Sheriff, Mr. Richard Beamish, and Mrs. Beamish gave a garden party, which was largely attended. The beautiful grounds were admirably suited for this very enjoyable entertainment, which proved a fitting *finale* to what on all hands was regarded as a most successful meeting.

[1] See THE LANCET, June 17th, p. 1677.

The Royal Hospital for Incurables, Dublin.

There is warm discussion over the proposal of the Royal Hospital for Incurables to increase its accommodation for tuberculous patients. At present there are only 40 beds for such cases, and it is intended to increase the number to 100 by the erection of a new pavilion in the hospital grounds. The hospital is situated in the suburbs of Dublin in some 15 acres of ground. Outside the unions, and a few beds in the Hospital for the Dying and in the Rest for the Dying, the hospital affords the only shelter in Dublin to persons incurably ill of tuberculosis. Unfortunately, the property owners and householders in the neighbourhood of the hospital have become alarmed at the danger of infection, and threaten legal proceedings to prevent the governors of the hospital carrying out their plans. This opposition would hardly have been taken seriously had not the Royal College of Physicians introduced, and passed, a resolution condemning the proposal of the hospital, not merely on the ground of the danger to the health of the district, but also because it "would be against the best interests of the unfortunate subjects who would be admitted." This resolution has naturally come in for severe criticism, as the only alternative for unfortunate persons suffering from tuberculosis is to die in their homes, where they are an infinitely greater danger to the public health than they would be in a properly conducted institution.

Royal Institute of Public Health.

Lord and Lady Aberdeen will attend the opening of the Congress, when the Lord Lieutenant, as patron, will instal Lord Dunleath as President. In addition to the various papers which will be read the following important subjects have been arranged for discussion in the different sections and conferences at the congress to be held in Dublin in August:—

Section A.—Preventive Medicine:—Subjects to be discussed: (1) Vaccination; (2) Aerial Convection of Diseases; (3) Effects of the Insurance Bill on Public Health.

Section B.—Chemistry and Bacteriology:—Subject to be discussed: (1) Typhoid carriers.

Section C.—Child Study and Eugenics:—Subjects to be discussed: (1) Open-air Schools; (2) Sanitary Condition of Schools in Ireland; (3) Medical Inspection of Schools.

Section D.—Comparative Pathology and Veterinary Hygiene:—Subject to be discussed: (1) Diseases Transmissible from Animals to Man.

Section E.—Engineering and Architecture:—Subjects to be discussed: (1) Tar-bound Macadam; (2) Disposal of House and Trade Refuse; (3) Treatment of Sewage, Effluent and Sludge Deposit.

Section F.—Housing of the Working Classes, Town-Planning, &c.:—Subjects to be discussed: (1) Discussion on the Operation of the Housing of the Working Classes Act and the Labourers Dwelling Act in Ireland; (2) Discussion on the Problem of Providing Dwellings for Workers in Dublin; (3) Principles of Town-Planning.

Section G.—Municipal and Parliamentary:—Subjects to be discussed: (1) The Limitation of Non-notifiable Infectious Diseases: (2) The Day Industrial Schools.

Section H.—Vital Statistics:—Subject to be discussed: (1) The Vital Statistics in Dublin. (Paper by Sir C. A. Cameron, C.B.)

Conference of Medical Officers of Health and Port Sanitary Authorities:—Subject to be discussed: (1) The Administration of the Public Health Act in Ireland as it affects Medical Officers of Health in Ireland.

Conference of Sanitary Inspectors:—Subject to be discussed: (1) Necessary Amendment to the Public Health Acts.

The Death of Sir George P. O'Farrell.

General regret is expressed at the death of Sir George Plunkett O'Farrell who recently retired from the post of Inspector of Lunatics in Ireland.

Expenditure on the Belfast District Asylum.

At a conference held recently in Belfast in connexion with the Charity Organisation Society, in which the work of the Belfast Branch of the Women's National Health Association of Ireland was brought forward in reference to tuberculosis, hygiene of schools, and infantile mortality, Professor J. A. Lindsay referred to the state of the primary school buildings, and said that in Belfast they devoted more attention to the sanitary condition of dairies, cowsheds, and even piggeries than they did to the sanitary condition of their primary schools. He sometimes thought that if he received a

visit from an inhabitant of another planet he would first take him to their magnificent asylum at Purdysburn and then to some of their primary schools. He thought his visitor would ask with amazement how they came to lodge their lunatics in palaces and to teach their children very often in hovels. There can be no doubt but that Professor Lindsay only expressed what is in everybody's mind who has a knowledge of public health, that it is time to call a halt to the tremendous expenditure of money in the magnificent villas at Purdysburn Asylum, where the results are, after all, naturally so poor, and to spend more of the public money in improving the hygiene of the schools and in trying to lower the high infantile mortality of Belfast, which was actually 143 per 1000 in 1910, while in London it did not exceed 103.

Royal Victoria Hospital, Belfast.

Dr. Thomas Houston has been appointed assistant physician in charge of the hæmatology and vaccine-therapy department, and Dr. J. C. Rankin, assistant physician for the X ray department. Dr. V. G. L. Fielden has been appointed anæsthetist, his position ranking with that of assistant physician or surgeon.—Hospital Saturday has realised already £925, and when completed it is expected that the sum will amount to £1000.—After paying expenses, £403 4*s.* were realised by allowing people to view the great ship in Belfast —the *Olympic*, and the sum was divided as follows: Royal Victoria Hospital, £151 12*s.*; the Mater Infirmorum Hospital, £75 16*s.*; the Queen-street Children's Hospital, £75 16*s.*; and the Ulster Hospital for Women and Children, £100.

Ulster Medical Society.

Dr. H. L. McKisack has been elected President; Dr. J. C. Rankin, secretary; Dr. John Rusk, treasurer; and Dr. W. L. Storey, librarian, for the session 1911–12.

Prevalence of Diphtheria in Belfast.

Diphtheria has practically been epidemic in Belfast for fully a year. During the past fortnight a local outbreak has occurred in the neighbourhood of Fortwilliam Park, one of the best residential quarters of the city. Sixteen cases have been sent to hospital.

The Antrim Infirmary.

At the last monthly meeting of this institution a resolution was unanimously adopted:—

That this meeting having considered the National Insurance Bill, now before the House of Commons, is of opinion that provision should be made in the Bill for payment to be made to the hospitals in respect of all insured persons receiving treatment, whether as in- or out-patients.

June 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Assassination of the Head Surgeon at the Hôtel Dieu.

Dr. Guinard, surgeon of the Hôtel Dieu at Paris, has been assassinated in the court of his hospital by one of his former patients, a Spanish journeyman tailor named Herrero, who fired five times upon him with a revolver. Dr. Guinard was carried immediately to the operating theatre and underwent the operation of laparotomy at the hands of his colleagues. One bullet was found to have penetrated the right kidney and perforated the intestine in eight places. Another had wounded the urethra and the prostate. After a long agony of eight days, during which his mind remained clear and consciousness was complete, the end came. As Dr. Guinard's death happened not only in the exercise of his office, but by reason of his office, the funeral was given by the municipality of Paris. The ceremony took place in the cathedral of Notre Dame, which became the scene of an imposing medical demonstration. A monument to Dr. Guinard will eventually be erected in the Hôtel Dieu. Among the funeral orations that of Dr. Segond produced a great impression. He spoke as the representative of the Société de Chirurgie, and did not hesitate to lay the responsibility for the crime on the mental attitude assumed by the public, from whose point of view the surgeon is a man who makes enormous sums of money and has only one aim—that of performing the largest possible number of operations. On the day of the death a political journal made the statement that the hospital surgeon does not take sufficient precautions with the poor people whom chance brings under his notice in his service, adding that the patients, though theoretically free to refuse a proposed operation, find themselves practically obliged to accept it, since in the case of refusal the only alternative is immediate dismissal. Under these conditions it is comprehensible, thinks the lay journal, that if the operation renders the subject infirm and unable to earn his livelihood, rage and a desire for revenge should spring up in the minds of neurotic subjects prone to melancholia and ideas of persecution. The circumstances which impelled the assassin to the commission of the crime are the subject of much comment at present among both the public and the medical profession. Before the magistrate who interrogated him the assassin declares that he had revenged himself on Dr. Guinard, who had maimed him for the rest of his life. Two years previously he had consulted Dr. Guinard for a fistula which had followed a large ischio-rectal abscess. Dr. Guinard laid open the fistula with the thermo-cautery. The patient was forewarned that temporary incontinence of the sphincter ani would be the consequence. As a matter of fact the incontinence did ensue, but did not prove temporary. The patient returned from time to time to complain to Dr. Guinard and consulted surgeons in other Paris hospitals. He asserts that Dr. Guinard put him off with irony and accused him of unmentionable habits. He declares also that in one of the hospitals which he visited an assistant assured him that his condition was caused entirely by a badly executed operation. The medical journals comment freely on these statements, of which the first is highly inconsistent with the gentle and kindly nature of Dr. Guinard, and the second, if exact, gives an added proof of the danger of imprudent explanations offered to patients by young and presumptuous students too ready to fail in respect to their former chiefs. Another incitement to such criminal acts is to be found in the idea that exists not unnaturally in the mind of the public (as a consequence of the new social laws which give a right to indemnity for whatever accident may occur) that for every misadventure which may happen to them some person or persons are necessarily responsible. It will soon be the case that if a person fractures his leg through slipping on a piece of orange-peel in the street he will sue the head of the street cleaning department. The magistrates who have awarded damages to patients on the ground that their medical attendant had failed to cure them have prepared the way for the criminal outrage of which an excellent surgeon has been the victim, a man whose great kindness and high character seemed to place him, even more than most, above such shafts of fortune. Dr. Guinard was the author of notable works on surgery of the abdomen and of the thorax and on cancer.

Disease and Mortality in the Army.

In the course of the discussion before the Senate on the War Budget, M. Richard Waddington remarked that disease among the soldiers was on the increase, a disconcerting statement in view of the continually increasing sacrifices offered in propitiation of the goddess Hygeia. It is true that in the last ten years mortality in the French army has been regularly diminishing. But its sum (4·26 per 1000) is still higher than that of Prussia (1·31), Hungary (2·82), and Italy (3·28). With regard to the morbidity returns, calculating from the number of soldiers entering the military hospital, it was in 1902 600 per 1000. At the present time it has reached 740 per 1000. The discussion which took place before the Senate on this subject shed a light on the many differing causes of this increase in the hospital admissions. There is, first, the dictates of humanity, whereby the rule for French soldiers is becoming more and more gentle through the growing influence on Parliament of sentiments of compassion for the humbler classes. Military doctors, exposed to attacks in the newspapers and complaints made in Parliament by the deputies of the Opposition, now much oftener than formerly admit soldiers desirous of entering the hospital for rest. A more serious reason is one to which attention has been directed by several senators; the diminution in the birth-rate in France, by limiting the choice of possible recruits for the army while the same numerical strength is to be maintained, renders it necessary to accept men of inferior physique, who in former days would have been rejected and who eventually constitute a large percentage of the hospital admissions. For an almost

identical total of men "*les conseils de révision*" in France have only 350,000 men to examine, while in Germany there are 1,200,000 to choose from, so that France has to enlist 70 per cent. of its contingent, Germany only 30 per cent., which gives that Power the chance of accepting only the robust. Lastly must be added the law which fixes the period of military service at two years instead of three years; a soldier's instruction compressed into two years instead of three becomes much more fatiguing and is more likely to produce exhaustion and illness. The report ends with a declaration which confirms the views expressed a long time ago by M. Delorme, inspector-general, to the effect that the morbidity of soldiers in a garrison town is influenced by the morbidity of the civil population of the town, with whom the soldiers are in frequent contact in restaurants, cafés, theatres, and hotels, while attempts to improve the state of the barracks and to supply pure water are almost nugatory if the town is unhealthy and the soldiers drink contaminated water in the cafés. The conclusion is that permission to quarter troops in towns where hygienic precautions are not taken must be absolutely refused. But such a measure will be extremely difficult to enforce, for the destination of regiments, which are a source of prosperity to the town shopkeepers, is generally dictated by political reasons.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Sea Air in the Treatment of Pertussis.

AT a recent meeting of the Budapest Royal Society of Medicine Dr. Szegö read a paper on Sea Air in the Treatment of Pertussis. He said that although there was still some diversity of opinion as to the specific cause of this disease, it was generally considered to be of an infectious nature, and accordingly in its treatment recourse should be had to the measures advised in virulent and contagious diseases as a class; the principal points to be observed being isolation of the patients, free ventilation and disinfection of their apartments, and sterilisation of clothing and other articles used by them. As to microbicide remedies, few of these were of any real service in pertussis, and those which have done such excellent service in surgical practice were not available in constitutional diseases. Inhalations of ozone have proved of much benefit in the hospital treatment of pertussis by Dr. Schiff, who attributed the favourable influence of this procedure to the antispasmodic properties of ozone. Dr. Szegö, however, believed ozone to be antiseptic as well and a true germicide in broncho-pulmonary affections. Sea air was known to be rich in ozone, an atmospheric condition which, in his opinion, accounted for the benefit derived from a sojourn at the seaside in the treatment of pertussis.

Chloride of Ethyl as a General Anæsthetic.

Dr. Manninger has published in the May number of the *Orvosok Lapja* an article recommending chloride of ethyl as a general anæsthetic in certain cases. He has found that this substance, which is also known as kelene, produces anæsthesia easily and rapidly, and is, moreover, free from the discomforts and dangers of chloroform and ether. It is procurable in tubes of known capacity containing from 25 to 50 cubic centimetres, a method permitting an exact knowledge of the amount used, which should not, as a rule, exceed 25 cubic centimetres (about six-sevenths of a fluid ounce). It may be given on a compress, usually in quantities of 5 cubic centimetres at a time (2 to 3 cubic centimetres for children and 6 to 10 cubic centimetres for alcoholic patients), and this dose may be repeated at intervals of five minutes during the operation, to the limit of 25 cubic centimetres. It will thus be seen that this anæsthetic is best adapted for short operations, though it may be advantageously employed in longer operations as a preliminary to chloroform or ether. By this means the discomforts and the dangers incidental to the inhalation of chloroform and ether are avoided, and a smaller quantity of the latter drugs may be used. Analgesia is produced by one or two inhalations of kelene, provided that these are sufficiently deep and that atmospheric air has not been directly inhaled; complete anæsthesia, which generally ensues in three minutes, is indicated by muscular relaxation and sometimes by dilatation of the pupils and by abolition of the corneal reflex. Anæsthesia continues for three minutes after inhalation of 5 cubic centimetres of kelene, when the dose must be repeated if the anæsthesia is to be prolonged, but complete analgesia persists for from 15 to 20 minutes after withdrawal of the drug, the patient regaining consciousness but suffering no pain during the completion of the operation, should it be deemed expedient to continue the work in this condition. Not the least of the advantages claimed for kelene anæsthesia is the absence of excitement in ordinary cases, though a slight excitement—not in the least comparable to that produced by other anæsthetics—is seen in hysterical and alcoholic subjects and when there has been direct inhalation of atmospheric air. Both the pulse and the respiration are normal in kelene anæsthesia. As a rule, there is no vomiting when the patient regains consciousness and no ill-effects are felt. An objection to kelene as a general anæsthetic is that it occasionally fails to produce the complete muscular relaxation essential to the performance of certain operations, such as reduction of dislocations, in which event the operator must hold himself in readiness to continue the work with another anæsthetic. The rapidity with which the patient recovers from the anæsthesia necessitates repeated doses during the operation, and as the amount given should not exceed 25 cubic centimetres kelene is unsuitable as the sole anæsthetic for use during long operations. Dr. Manninger, however, considers that at the commencement of long operations it is useful as a preliminary to the administration of chloroform or ether.

June 24th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"*Father Tiber Salutes Father Thames.*"

THE coronation of King George V. and Queen Mary, at which the whole world, far and near, has assisted, found no nationality more cordially interested than Italy, sincere as she has ever been in her admiration of British institutions, profiting as she has not failed to do by British precedent, and grateful as she will always remain for British participation in her "Risorgimento," promoted as that was by British sympathy as effective as it was unselfish, and by British support as unobtrusive as it was opportune. In all her great centres of population she was worthily represented at the symposia held on June 22nd by the English-speaking colony, joining enthusiastically in the "toast of the evening" and supplementing the official oratory by eloquent contributions of her own. At more than one of these the reciprocal indebtedness of the two peoples in the domain of science was pointedly referred to—British medicine, for instance, in its later development repaying what it owed to Italian in the post-Renaissance Universities of Padua, Bologna, and Pisa. The first-named of these schools has no prouder boast than that of having inspired the English William Harvey; and if her consummate anatomist and teacher, Giulio Casserio, earned the gratitude of relays of students from every European nationality, that gratitude found no finer expression than in the epigrams of the Scottish Arthur Johnston, body physician to King Charles I., to whom the famous "Anatomica Sectio à Julio Casserio Patavii Exhibita" owes an immortality only to cease with the Latin tongue.

Dr. Augusto Murri.

In this connexion it is opportune to mention that the illustrious head of the clinical staff of the Bologna school, Professor Augusto Murri, known to readers of THE LANCET more particularly for his contributions on the pathology of the brain, has not suffered seriously from the terrible railway accident which on June 20th caused three deaths out of the 33 passengers who were more or less injured. The scene of the disaster was San Benedetto del Tronto, a station on the Adriatic seaboard, some 30 miles south of Ancona, and Professor Murri was in the train *en route* to Teramo, to which he had been summoned in consultation. Providentially he was in a first-class compartment which

seems to have suffered but partially from the collision, and beyond a superficial lesion and the inevitable "shock" he was so little the worse as to be able to despatch a reassuring telegram to his wife and to give some assistance to his less fortunate fellow passengers. The latest accounts from Bologna represent his condition as "satisfactory," though his years (more than three score and ten), added to domestic trials fresh in the mind of the public, still warrant anxiety on the part of his many friends and pupils.

St. Andrews University and the Vatican.

Scotland's "Mater Studiorum," which is to celebrate her 500th birthday next September, is another British institution in which Italians are interested, if only for the fact that, like Glasgow and Aberdeen, it started under the ægis of the Holy See, which will be officially represented at the celebration in question. The current number of the *Vox Urbis*, a monthly periodical in the Latin language, published with the approval of the Vatican, contains an article, "De Urbe Sancti Andreae ejusque Studiorum Universitate," which will gratify the many graduates, medical and other, of that seat of learning, for its accurate historical details and its glowing eulogy of the town and its school. Four effective illustrations representing the ruined cathedral, the remains of the castle, and the United Colleges of SS. Salvator and Leonard and of S. Mary, supplement the letterpress, which, while highly creditable to the scholarly priest who contributes it, does little more than indicate the "Royal and ancient game" of which St. Andrews used to be called the Mecca. Even the flowing and flexible Latinity of S. Jerome may be excused for not venturing beyond an allusion to the "pera clavicularum" (golf-bag). The writer, however, might have found a more classical equivalent for "Dundaeum" in alluding to the College of Dundee. "Taodunense" (derived from the "dun" or hill on the Taus or Tay) would have had the sanction at least of George Buchanan and also of that distinguished physician and Latin poet, Dr. Archibald Pitcairne.

June 24th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

The Census in South Africa.

THE Census in South Africa was taken on May 7th. It is to be regretted that it was not taken on the same day as in the other overseas dominions and in the mother country. The explanation officially given is that owing to the inauguration of Union the Government was unable to make the necessary arrangements for it to be taken earlier, although it is understood that much of the preliminary work had been done prior to Union. The Census was taken under the directorship of Mr. J. B. Moffat, Commissioner of Taxes for the late Cape Colony. The post was originally offered to Dr. A. J. Gregory, the medical officer of health for the late Cape Colony, immediately after Union, but was declined by that officer in the absence of some assurance from the Government as to his official future in public health under Union. From a statistical standpoint it is unfortunate that Dr. Gregory was unable to see his way to accept the appointment, for his prolonged experience in such work and his special statistical attainments clearly marked him out as the one man in South Africa especially fitted for it. From a public health standpoint, however, the profession and the public are thankful that Dr. Gregory did not take up the directorship of the Census, for had he done so he would have been shelved from public health work, and it is generally recognised that at the present critical juncture in the history of public health administration in South Africa he could not well be spared. Dr. G. Pratt Yule, the medical officer of health for the late Orange River Colony, acted as supervisor of the Census for his province, but now that the actual Census is taken it is understood he will not be required to assist further. Indeed, as far as is known, Mr. Moffat is not to be assisted further by any medical expert, and if this is true his report is hardly likely to be of the value to public health workers in South Africa that might otherwise have been expected. At the time of writing a few of the returns for individual towns have been published, and indicate the enormous difficulties that health officers are faced with in South Africa in attempting to furnish vital statistics for their areas in inter-census years owing to the effects of emigration and immigration. Thus the returns for East London show that the total population of the municipality is 21,777, of which number 12,552 are Europeans and 8725 non-Europeans, a decrease on the previous Census taken in 1904 of 2122 Europeans and 1821 non-Europeans. The total population for the whole division, urban and rural, is 47,697, comprising 18,179 Europeans and 29,518 non-Europeans, a decrease on the previous Census of 1614 Europeans and 410 non-Europeans. Still more striking are the statistics for Cape Town and other municipalities in the Cape Peninsula. In Cape Town there are 29,933 Europeans and 37,237 non-Europeans, or a total of 67,170 persons, as compared with 44,203 Europeans and 33,465 non-Europeans, or a total of 77,668 persons in 1904. In the suburbs of Cape Town, also, there has been a great reduction in the number of Europeans and a slight increase in the number of coloured inhabitants. Indeed, judging from the figures already published, it would seem likely that there is a large reduction in the European populations of all the coastal towns, and also of most urban centres, not depending on the mining industry—doubtless due to the period of financial depression from which South Africa is only now slowly emerging.

Medical Council Muddle.

It will be remembered that some time ago the majority of the members of the Free State Medical Council resigned as a protest against aspersions cast on that body by General Hertzog. The sequel has been somewhat amusing. It appears that up to the middle of April the Government had taken no steps to fill the vacancies, but that the secretary had received instructions from the Minister to register, although quite illegally, any applicant for registration whose qualifications would otherwise entitle him to registration in accordance with the laws of the province. Four gentlemen were, however, eventually appointed as Government nominees, none of the former nominees being reappointed. These with two representatives of the old council who did not resign form a quorum. Another three months had to elapse before an election could be held to fill the vacancies caused by the resignation of certain elected members of the council. In compliance with a request from the permanent head of General Smuts's department that a meeting should be called as soon as possible to deal with pressing business, including the approving formally of the registrations effected by the secretary in the interim, members assembled on April 28th. But after debating the matter for about an hour it was discovered that the meeting had been illegally convened, and that consequently no business could be transacted thereat. Under the regulations of the council it appears that only the president can call together the members on any other day than that fixed by the regulations, which is the second Friday in the month, and so there was nothing for it but to dissolve the meeting until the following month, when the council confirmed the registrations unlawfully effected by its secretary.

June 3rd.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Professor Bernhard Fränkel, who has charge of the Clinic and Policlinic for Diseases of the Throat and Nose intends to retire at the close of the current summer session being in his seventy-fifth year.—*Florence:* Dr. Antoni Pellegrini has been recognised as *privat-docent* of Operativ Medicine.—*Leipsic:* Dr. Payr, professor in the University o Königsberg, has been appointed to the chair of Surgery vacated by the death of Professor Trendelenburg.—*Modena* Dr. G. Tarozzi, professor in Cagliari, has been appointe to the chair of Pathological Anatomy and Histology.—*Parma:* Dr. Giorgio Ballerini has been recognised as *priva docent* of Midwifery and Gynæcology.—*Turin:* Dr. Saver Verson of Pavia has been recognised as *privat-docent* of Hi tology.—*St. Petersburg (Women's Institute of Medicine):* D A. Rubel has been recognised as *privat-docent* of Medicine.—*Vienna:* Dr. Otto von Frisch has been recognised as *priva docent* of Surgery, Dr. Robert Cristoph Peroletti as *priva docent* of Midwifery and Gynæcology, Dr. Bertold Spitz as *privat-docent* of Odontology, and Dr. Robert Stigler *privat-docent* of Physiology.

Obituary.

SIR RUBERT WILLIAM BOYCE, M.B. LOND., F.R.S.,

HOLT PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL; DEAN OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

IN our issue of last week we briefly announced the death of Sir Rubert Boyce on June 16th after a short illness. Rubert William Boyce came of Irish stock. His father, the late R. H. Boyce, C.B., was principal surveyor of buildings in the Consular Service, and both his grandfathers were country practitioners of medicine in Ireland. He studied at University College, London, Heidelberg, and Paris, and qualified in 1888 as L.R.C.P. Lond., M.R.C.S. Eng., obtaining the M.B. degree of the University of London in the following year. Whilst working at University College, London, he showed considerable powers of scientific investigation, and in the early "nineties" he published various papers on the pathology of the nervous system, which earned for him the Fellowship of the Royal Society. During this time he also wrote a "Text-book of Morbid Histology," and was part author of "A Handbook of Pathological Anatomy (Museum Pathology)." In 1894 he was appointed to the newly created George Holt chair of pathology in the University College of Liverpool, and thenceforward became intimately associated with that city.

"The new post gave him an opportunity to show that, besides possessing scientific attainments of a high order, he had a great talent for organisation. This was displayed at first in general work for University College, and for the separate University of Liverpool into which that College was shortly elevated. Later he became, with his colleague, Sir Ronald Ross, especially identified with the Liverpool School of Tropical Medicine, of which he was the twin founder with Sir Alfred Jones. He served personally on expeditions of the school on many occasions. He went to Egypt and inspected the result of Sir Ronald Ross's and Dr. Pressat's successful work in Ismailia, which is now comparatively free from malaria. With the consent of the American Government he investigated a serious outbreak of yellow fever at New Orleans. Again, at the special request of the Colonial Office, he visited British Honduras, and drew up an exhaustive report of sanitary conditions there and of prophylactic measures against the dangers of yellow fever. He also visited Central America, and in later years he made tours of the West Indies and West Africa. He was indeed absorbed in tropical research.

The following appreciation of Sir Rubert Boyce is written by one of his oldest and most intimate friends, Professor J. M. Mackay:—"The news of the premature death of Sir Rubert W. Boyce will come like a shock to many, not only in our own country, but also in the tropical and adjacent regions of the Empire, and indeed in scientific and medical circles everywhere. The foundation of the Liverpool School of Tropical Medicine is an event which reaches beyond the annals of medicine. It is the dawn of a new era and a new hope for the tropical world. The development of those countries, the security of life for the European planter, trader, missionary, and administrator, as well as for the native, appear to be staked upon the success of such researches as this Liverpool institution first organised and promoted. The vast issues were clear to the mind of the extraordinary man who devoted his genius and life to this enterprise. Entirely Irish by origin, the son of a well-known public servant, an architect in China, educated himself for a short time at Rugby, afterwards in France, he acquired an education very little on the beaten lines. It was when at work with Sir Victor Horsley in the laboratories in University College, London, that he began to show promise of his real powers. His early scientific work was noted by those who had eyes to discern. His appointment to the new chair of pathology at Liverpool gave him his opportunity and sphere. Everything there on the high educational ground was in the origins and in the making. Boyce had youth, exhaustless, boundless energy, indomitable persistence, and a clear and daring vision. Besides, upon no experience whatever, he found he had the practical gifts as well. He learned to handle men, and in particular what is almost impossible for the ordinary academic spirit, he grew into intimate, easy, and friendly relations with men of business of every sort. Seizing upon the form of certain schools already established in Liverpool, whereby the city and University coöperate through representatives of the corporation, the academic staff, and governing body, or of others interested by professional sympathy, he created first the School of Hygiene for the training in public health on all points, human and animal. It was the natural expansion of his chair of pathology into the actual world. He soon had municipal pathological work inside the university pathological department also. The chief danger in a provincial city is the multiplication in a hurry, and with a waste of money, of feeble organs here and there, instead of installing concentrated and powerful spiritual batteries. Of course, this was in due time accomplished in the University. It was the creation, however, of the Tropical School which swept open for Boyce a boundless prospect. Here he had associated with him Sir Alfred Jones, a shipowner trading with West Africa, who was himself only emerging at the time, but as Boyce used to say, 'Alfred Jones is a poet.' Boyce's tributes to Sir Alfred Jones living and dead were constant and unstinted, and the union of science and practice on great imaginative lines had remarkable results. The annual income of the Liverpool School of Tropical Medicine now amounts to some £8000, besides the fully endowed chair of tropical medicine, the gift of Sir Alfred Jones.

"The appointment of Professor Ronald Ross to the chair was yet another stroke of genius, for Ross was not yet fully recognised. To carry forward their work the money had to be obtained. In a country where there are little or no public subventions the only course open is the familiar way of all the public charities. Boyce's success as a beggar was marvellous, and he conducted his campaign with shrewd and infinite humour. It became a game where none was more amused than the wealthy and generous man who meant to be close and found he had subscribed handsomely. The two promoters of the school believed in a wide subscription-list as indicative of sound general health and public interest. Scientific expeditions were constant, and a programme which had started with the one item of malarial fever soon included all tropical medicine. Boyce visited in due time New Orleans, upon an outbreak of yellow fever there, British Honduras, West Indian Isles, British Guiana, and West Africa. These were successful missions, for besides his scientific and special interests nothing human or natural was unwelcome to him. He met on these tours minds of every shade, and his own judgments, which he revised upon the pressure of new material, became vivid and instructive. His success, scientific and financial, at the Colonial Office and with Governors and officials was remarkable. The story of these distant visits and missions, and the conclusions which he thought ought to be drawn, have been published in three recent works, in addition to all the bulletins regularly published from the school, while his signal achievements in the Liverpool laboratories are well known. The network of his propaganda was wide-flung and close-meshed. The Liverpool school became a pattern, an inspiration, and a source of light for many lands and workers. It is the most famous intellectual achievement in the city.

"Meanwhile he was in the forefront of another great educational movement—the establishment of an independent University in Liverpool on advanced and varied lines—and spent probably his happiest public hours amid a small band of colleagues and friends at the University Club. The club became a centre for such as cared to share in the University movement or to promote any high educational advance. It started on next to nothing. Boyce's practical gifts here, even to the house furnishing, were invaluable. His manifold enterprises had inevitably roused opposition, but here he was at home among friends and allies. His personal influence and the confidence he inspired attracted sympathetic citizens of all parties and creeds into membership with communion and coöperation. The University of Liverpool in a few years was launched from this dock. About this time a great shadow darkened his life, for he lost his wife, who died after the birth of her first child and with whom he had lived most happily. To commemorate her life her father, a local shipowner, by a magnificent gift to the University, provided new laboratories, which became the home of the Tropical School, and founded a new chair of bio-chemistry, the first in this country. Here was another instance of Boyce's keen vision which went to the heart of the last results of contemporary

foreign medicine. Developments no less striking followed at Liverpool, such as an Institute for Cancer Research, and an Institution of Tropical Research in regard to trade and industry and agriculture. This last splendid conception was doomed, it might be said, in advance, owing to the lack of trained investigators, but in all the movements Boyce played a leading part. Our university system of daily prescribed doses, and repeated examinations upon them, does not breed often men of this quality.

"In figure Boyce was fair, small, light, and active. During the brief tenure of his life in Liverpool, some 15 years in all, and only nine in full health, he had as his home a delightfnl nook near to one of the great public parks. There he entertained with wide hospitality visitors from many cities, countries, and climes. After a paralytic stroke six years ago—which shattered his health, temper, and balance—he recovered very gradually, and as he grew better he devoted himself wholly to the study of the tropics. It was the passion of his life. His end was sudden and peaceful. Only the day before he was entertaining a West African magistrate, originally a medical man like himself, and two of his old colleagues and close friends. His vivacity and intellectual sympathies, his opinions on nature and man, his criticism of antiquated and futile methods, whether on the Coast or in the universities, were as fresh, searching, piquant, and independent as before. It was the dying flicker. The simplest record of his life, the barest account of his solid achievements, will perpetuate the memory of a rare and extraordinary mind."

Sir Rubert Boyce was only 48 years of age at his death, which, despite the serious breakdown alluded to by Professor Mackay and his known delicacy of health, was quite unexpected. The day before his death he was at work in the Thompson Yates laboratories with his accustomed zeal. On June 7th he was at a banquet given by Mr. W. H. Lever, the chairman of the Liverpool School of Tropical Medicine, to speed Professor Newstead on his expedition to Nyasaland and to welcome Professor J. L. Todd and Professor Wolbach home from their expedition to the Gambia and French Senegal. Sir Rubert Boyce, in responding to the toast of "Tropical Medicine and Commerce," then expressed the hope that soon the dream of the late Sir Alfred Jones would be realised in the establishment of a chair of parasitology at the University of Liverpool in memory of the late Dr. Walter Myers. His last public utterance, therefore, was fittingly in support of the cause for which he lived and died.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ernst Julius Remak, privy councillor and extraordinary professor of neurology in the University of Berlin. He had been Westphal's assistant in the Charité in the "seventies." His contributions to medical literature were mostly connected with electro-therapeutics. He was nearly 62 years of age, and he died in a nursing home in Wiesbaden. His name reminds us of that of his illustrious father, Dr. Robert Remak, the anatomist, who was the first Jew who was admitted to the teaching staff of the Berlin University, a special decree being granted by King Frederick William IV. for the purpose.—Dr. Ludwig Kerschner, professor of histology and embryology in the University of Innsbruck.—Dr. Adolf Schmidtmann, curator of the University of Marburg and for many years a very prominent and active government sanitary councillor. His special work was mainly that of superintending the water-supply and drainage of the city.—Dr. A. Valentin, honorary professor of laryngology and otology in the University of Berne, aged 65.—Dr. Stanford E. Chaillé, professor of physiology and pathological anatomy in Tulane University of Louisiana, New Orleans.—Dr. Maurice Claudot, formerly Inspector-General in the French Military Medical Service.—Dr. A. Guinard, surgeon to the Paris hospitals.

PROPOSED NEW COTTAGE HOSPITAL FOR AXMINSTER (DEVON).—It is proposed to erect a new cottage hospital for Axminster, as the old institution is not up to modern requirements. The sum of £1830 has been already received towards the building fund, and it is hoped that the work will shortly be commenced.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. H. Budd (Section II.), St. Mary's Hospital; R. F. Eminson (Sections I. and II.), Charing Cross Hospital; and A. A. E. Newth (Sections I. and II.), Westminster Hospital.
Medicine.—N. S. Adler (Section I.), Berlin; L. K. Edmeades (Section I.), Guy's Hospital; R. F. Eminson (Sections I. and II.), Charing Cross Hospital; C. C. Messiter (Sections I. and II.), St. Bartholomew's Hospital; A. A. E. Newth (Sections I. and II.), Westminster Hospital; and G. H. Varley (Sections I. and II.), Oxford and St. George's Hospital.
Forensic Medicine.—R. F. Eminson, Charing Cross Hospital; C. C. Messiter, St. Bartholomew's Hospital; and A. A. E. Newth, Westminster Hospital.
Midwifery.—H. Cox, Birmingham; R. F. Eminson, Charing Cross Hospital; A. A. E. Newth, Westminster Hospital; and J. E. Taylor, Leeds.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—H. H. Budd, R. F. Eminson, A. A. E. Newth, and G. H. Varley.

UNIVERSITY OF OXFORD.—Dr. C. Theodore Williams, honorary Fellow of Pembroke College, has offered to the University a sum of £2500 upon trust to apply the income to the encouragement of the study of pathology and bacteriology in relation to medicine. It is proposed to found two scholarships, each tenable for two years. A decree has been introduced in Convocation gratefully thanking the donor.

DONATIONS AND BEQUESTS.—Under the will of the late Miss Anna Thorne Harris of Plymouth the South Devon and East Cornwall Hospital at Plymouth will receive £2000, the South Devon and Cornwall Institution for the Blind at Plymouth £1000, and the Plymouth Royal Eye Infirmary and the Plymouth Public Dispensary £500 each.—Miss Burrell of Botley, Hants, has undertaken to defray the cost of building a new out-patient department for the Royal South Hants and Southampton Hospital at a cost of more than £10,000.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The seventieth annual meeting of this association will be held on Thursday and Friday, July 13th and 14th, in Dublin, under the presidency of Dr. William R. Dawson. On Wednesday members will be given an opportunity of inspecting the Richmond Asylum, St. Patrick's Hospital, and the Stewart Institution. The annual meeting will commence at 11 A.M. on Thursday at the Royal College of Physicians, and the presidential address will be delivered after luncheon. The following papers will then be read:—Dr. G. M. Robertson (Morningside), Treatment of General Paralysis, with a view to Cure; Dr. W. Graham (Belfast), Psycho-therapy in Mental Disorders; Dr. M. J. Collins (Ewell Colony) will read a paper upon Causes of Sudden Death in Epilepsy and Some Points in the Treatment of Epilepsy; Dr. R. R. Leeper (St. Patrick's Hospital), Note on Hereditary Insanity from a Practical Standpoint. At 7.30 P.M. the annual dinner will be held at the Royal College of Surgeons, St. Stephen's Green. On Friday, commencing at 9.30 A.M., at the Royal College of Physicians, the following papers will be read:—Dr. T. Drapes (Enniscorthy), the Personal Equation in Alienism; Professor A. C. O'Sullivan, F.T.C.D. (Dublin University), Case of Degeneration of the Spinal Cord, following Infection with B. pyocyaneus; Professor J. Shaw Bolton (Wakefield), Certain Observations on the Morbid Histology of General Paralysis; Dr. Colin McDowall (Cheddleton) and Dr. W. T. Sewell (Newcastle), Clinical Evidence *re* the Toxic Nature of Insanity; Professor W. H. Thompson (Dublin University), the Chemical Regulation of Neuronic Function; Dr. Edward Mapother (Long Grove), Mental Symptoms in Association with Choreiform Disorders; Dr. J. J. Fitzgerald (Cork), Trephining in Mental Diseases; Dr. Ivy Mackenzie (Glasgow), Salvarsan in Nervous Disease: with an account of its Effect in Syphilitic and Parasyphilitic Conditions. From 4.30 to 7 P.M. a garden party will be held at the Zoological Gardens, Phœnix Park; and various other social arrangements have been made by the reception committee. The honorary general secretary is Dr. C. Hubert Bond, 6, Cavendish-square, London, W.

KING EDWARD MEMORIAL HOSPITAL, EALING.—The opening of the new hospital in Mattock-lane will take place on Saturday, July 15th, at 4 P.M., when H.R.H. the Princess Christian of Schleswig-Holstein has consented to perform the ceremony. Tea and coffee will be served at 4.45. Visitors are requested to be in their places by 3.45 at the latest.

PRESENTATION TO A MEDICAL PRACTITIONER.—At Ottery St. Mary (Devon) the vicar, the Rev. J. Metcalf, on behalf of 525 subscribers, recently presented Mr. Francis Mortimer Reynolds, M.B., C.M. Edin., with a silver rose bowl and an album containing the names of the subscribers as a mark of respect and esteem on the occasion of his leaving the neighbourhood after having practised there for the past 25 years.

CHELSEA HOSPITAL FOR WOMEN.—Lord Cadogan has presented over an acre and a quarter of land to the hospital for purposes of extension. The accommodation for in-patients is at present inadequate, and it is also impossible to provide for the needs of out-patients and to house the nurses satisfactorily. The land given by Lord Cadogan is within a short distance of the present building.

MEDICO-LEGAL SOCIETY.—The annual general meeting of this society will be held at the Holborn Restaurant on Thursday, July 20th, at 6 30 P.M. The annual dinner will be held at 7.30 P.M., when the President will be in the chair. The price of tickets is 10*s.* 6*d.* each. Members intending to be present are desired to give early notice to Dr. William A. Brend or Mr. Roland Burrows, the honorary secretaries.

DEVON COUNTY ASYLUM.—At the last meeting of the Devon county council the asylum committee reported in favour of the appointment of a fifth medical officer for the County Asylum, who should also undertake the duties of pathologist and bacteriologist. It was also suggested that a laboratory should be provided. The county council adopted the report of the committee. It was stated that at present there were 1338 patients in the institution, 568 males and 770 females.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.—The next meeting of this Congress will take place on Thursday and Friday, July 13th and 14th, at Keble College, Oxford. It will be preceded by an unofficial dinner in Keble Hall on July 12th, at 7.30 P.M. Medical men when sending in their names as prospective attendants at the Congress to the honorary secretary, Mr. Sydney Stephenson, 33, Welbeck-street, London, W., should enclose the attendance fee of half-a-guinea, and should also state whether they desire rooms to be reserved for them in Keble College, the charge for board and lodging in the College being 7*s.* 6*d.* The Congress will be opened at 10 A.M. on Thursday, July 13th. Addresses will be made by Professor Arthur Thomson on the Filtration Angle, Dr. Lieven on "Salvarsan," and Major R. H. Elliot, I.M.S., on Trephining in Glaucoma. In the afternoon there will be tea in Balliol College garden, and at 7.30 P.M. the official dinner will take place in Keble Hall with Sir William Osler in the chair, followed by dessert in the Junior Common Room at Keble College. On Friday, July 13th, addresses will be delivered by Professor Francis Gotch, F.R.S., on Dark Adaptation, and Dr. Harold Low on Narcotic Drugs as Adjuvants to General Anæsthesia; and a lantern demonstration by Dr. StClair Thomson of the relationship of diseases of the nose and accessory sinuses to affections of the eye and orbit will be given. In the afternoon there will be tea at the Eye Hospital, and a visit will be made to the Clarendon Press and the Colleges, followed by dinner in Keble Hall, and a smoking concert in the Junior Common Room at Keble College. On both days there will be demonstrations in the morning in the Department of Physiology and in the afternoon at the Eye Hospital. On Thursday afternoon Dr. Lewis Ziegler (Philadelphia) will demonstrate: (1) the Treatment of Ectropion and Entropion by galvano-cautery puncture, (2) that of Lacrymo-nasal Disease by rapid dilatation, and (3) Iridodesmy with the knife-needle; and Mr. Charles Higgens (London) will perform Toti's operation of Dacryocystorhinostomy. On Friday afternoon cases treated by salvarsan will be shown by Dr. R. Granville Waddy, and Dr. Lieven will demonstrate the intravenous injection of that preparation. On Saturday, July 15th, there will be river excursions to Reading and Henley.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Coronation.

PARLIAMENT was not sitting during the period of the Coronation festivities in London last week.

National Insurance Bill.

Many amendments have been put down to the National Insurance Bill. Mr. HAROLD SMITH has put down amendments to Clause 14 in the same terms as those of Dr. ADDISON reported in THE LANCET of June 24th. Dr. ADDISON has intimated his intention of moving the insertion of the following subsection in Clause 16:—

"Notwithstanding anything herein the mother shall decide whether she shall be attended by a registered medical practitioner or by a duly certified midwife and shall have free choice in the selection of such practitioner or midwife, and in the case where a midwife requires the aid of a registered medical practitioner the Local Health Committee shall make arrangements subject to the approval of the Insurance Commissioners for the payment of such registered medical practitioner."

HOUSE OF COMMONS.

MONDAY, JUNE 19TH.

National Insurance and the Supply of Drugs.

The Marquis of TULLIBARDINE asked the Chancellor of the Exchequer whether he was aware that a per capita payment for the supply of drugs would deprive insured persons of many remedial agents; and whether, in the interests of insured persons, the Commissioners would frame a scale of prices based on the cost or market price of the commodity; and whether, in that event, insured persons would be permitted to obtain their supplies from any registered chemist accepting such a scale.—Mr. LLOYD GEORGE replied: The supply of drugs is, under the Bill, a matter for the approved societies and the Local Health Committees, who need not adopt a per capita system. The Insurance Commissioners are not specially empowered to interfere, except in so far as they must, as a condition of approving of any society, satisfy themselves that the society is providing the benefits prescribed by the Bill.

Famine Deaths in India.

Mr. GINNELL asked the Under Secretary of State for India to state the number of deaths of human beings from starvation in India in each of the last ten years and in the whole period.—Mr. MONTAGU replied: The information asked for by the honourable Member is not forthcoming from the mortality returns of British India, as they do not show "starvation" as a separate cause of death. In times of famine special efforts have been made to secure a correct record of all deaths attributable directly to want of food, but without much success. In the 1907-8 famine in the United Provinces not more than 11 deaths were thus recorded. Famine mortality is due to the consequences of insufficient food, not to entire want of it.

Plague in India.

Mr. GINNELL asked the Under Secretary of State for India how many of the 6½ millions of human beings known to have died from plague in India within the last ten years died from bubonic plague and how many from pneumonic plague; and whether the Government proposed to convene an international medical conference in India next winter to devise means of counteracting this scourge.—Mr. MONTAGU answered: The returns of plague seizures in India do not distinguish cases where the symptoms are bubonic from those that take septicæmic or pneumonic forms. But it may be said that more than 90 per cent. of the cases take the bubonic form. There is no intention of convening an international medical conference in India to deal with the question of plague prevention. The scientific problems have already been elucidated by the Joint Commission organised by the Royal Society and the Lister Institute, and the practical application of the Commission's discoveries is a matter for the Indian Government.

TUESDAY, JUNE 20TH.

Deaths from Chicken-pox.

Mr. CRAWSHAY-WILLIAMS asked the President of the Local Government Board whether any inquiry was made in cases of certified deaths from chicken-pox with a view to ascertain if such cases of deaths in children were in reality due to small-pox and not chicken-pox, as alleged by the Registrar-General in his Forty-sixth and other Reports; and whether such inquiry had confirmed the opinion generally held by medical authorities that deaths from chicken-pox were of very rare occurrence indeed.—Mr. BURNS wrote in reply: The doctor who grants a death certificate is required to state the cause of death, and, as a general rule, no inquiry is made to check the correctness of his statement. When small-pox is prevalent in a district, chicken-pox is frequently added to the list of notifiable diseases with the object of discovering whether any cases supposed to be chicken-pox are really small-pox. In such cases it would rest with the medical officer of health of the district to make such inquiries in regard to any deaths certified to be due to chicken-pox as he considered necessary.

The Spread of Measles in Schools

Mr. SNOWDEN asked the President of the Local Government Board whether, under the regulations issued by the chief medical officer of the Board, children might attend the public schools, although they came from homes in which at the time other children were suffering from measles; and whether he was aware that the school attendance officers,

acting under instructions from the local medical officer of health, whose action in this matter was governed by the Local Government Board regulations, insisted upon a child attending school if it had once had measles, although its brothers and sisters might be suffering from the disease; and, in view of the loss of child life from measles, would he take steps to make the regulations for dealing with this disease more stringent.—Mr. Burns wrote in reply: No regulations on this subject have been issued, but a memorandum was prepared jointly by the medical officers of the Local Government and Board of Education, which contains rules for the guidance of the officials concerned. These rules are based on present medical knowledge, and I am advised that such knowledge would not justify a modification of the rules in the direction suggested in the question.

MONDAY, JUNE 26th.

The Composition of Patent Medicines.

Mr. CHANCELLOR asked the Secretary of State for the Home Department whether he had received a communication from the Royal College of Physicians recommending that manufacturers and vendors of patent medicines should be compelled to print on the labels of the bottles or other vessels the exact composition of such medicines and the amount of each constituent; and whether, if he gave effect to this recommendation, he would take steps to make the rule applicable to the various vaccines and sera imported from abroad and those manufactured in this country.—Mr. CHURCHILL replied: I have been in correspondence with the Royal College of Physicians on this subject. I have no authority to take the steps suggested, but I think that the question of the conditions of the sale of patent medicines might usefully be considered by a Select Committee next session. I cannot at present express any opinion as to whether the inquiry should be extended to vaccines and sera.

National Insurance Topics.

Mr. JOYNSON-HICKS asked the Chancellor of the Exchequer whether he was aware that the medical profession was practically unanimous in asking for a wage-limit beyond which free medical benefit should not be given; and whether he could state, for the information of the House, his exact reasons why such wage-limit was impossible.—Mr. WEDGWOOD BENN (answering on behalf of Mr. LLOYD GEORGE) said: I fear it would be impossible to argue a complicated question such as this is in reply to a Parliamentary question, but I will refer the honourable Member to the passages dealing with the subject in my right honourable friend's speech on the second reading of the Bill on May 29th.

Mr. JOYNSON-HICKS also asked whether the Chancellor of the Exchequer had yet considered whether, in the management of consumption sanatoria and regarding patients who proved to be incapable of recovery, they would be kept in the sanatoria or sent home to die, as was the very common practice at the present time, thus spreading the disease over a wider circle.—Mr. WEDGWOOD BENN answered: The administration of sanatorium benefit will be in the hands of the Local Health Committees.

Home Office Administration.

On the House going into Committee of Supply on the Home Office vote,

Mr. J. W. HILLS called attention to the prevalence of lead poisoning. In 1896 the number of cases of lead poisoning in the Potteries was rather more than 400 a year. As a result of legislation, in the next four years they dropped to half, or 200 a year. As a result of further legislation, by 1901 they had dropped to about 100 a year. For the last ten years there had been no real decrease in the cases of lead poisoning in the Potteries. During the last eight years the figures had remained exactly as bad as they were. There did not seem very much hope under present conditions of their getting better. It might be thought by the Committee that the figure of 100 cases of lead poisoning a year was not a very large figure. He would grant that it was not, but the total harm to the community was not measured by the actual figure. Lead poisoning was a very insidious disease, and one which in its early stages was very hard to trace. Above all, its effect on women was extremely deleterious. It affected them in a very strange and remarkable way, and the result was that where women were exposed to lead poisoning their liability to miscarriage was very largely increased and stood at about three times that of the average of the community. He was inclined to think that the only real solution would be found by prohibition, either partial or complete, of the use of raw lead glazes, and the report of the Departmental Committee on Lead Poisoning pointed out that in connexion with a great many articles, and especially cheap coarse articles, the use of non-lead glazes was just as cheap as raw-lead glazes. He did not believe that this country alone could prohibit the use of lead glazes. The only way the subject could be adequately dealt with was by international agreement on the lines of prohibition, as was the case with white phosphorus in the match trade. He would urge the Home Secretary to take advantage of the next International Labour Conference to ventilate the subject and see whether it was not possible to get some international agreement in order to stamp out this evil. He believed that if a determined effort was made to tackle this evil a solution would be found.

Mr. GILL in the course of a speech referred to the Workmen's Compensation Act and medical referees. When Lord Gladstone was Home Secretary and the House of Commons was considering the Act, the point was pressed upon him that there ought to be State medical referees appointed who were not engaged in private practice. Lord Gladstone at that time had said he thought that it would be too expensive, that the cases were comparatively not numerous, and that it would cost the State too much, as medical referees could not be got without paying them a very large salary. Lord Gladstone, however, made a promise that an experiment should be tried by the appointment of a few such medical referees, but that promise had not been yet carried into effect. There was a very great dissatisfaction throughout the whole of the country in regard to the question of medical referees. As a rule they were engaged in private work, and naturally it was suggested that they could not very well be free from bias. There were medical referees engaged by insurance companies—not, of course, in the cases in which they acted as medical referees, but in other cases—and seeing that they got part of their income by examining persons who had been injured and that they were employed by the companies there must be a natural bias in that direction. But whether there was a bias or not there was a feeling amongst the workers that they were not getting fair treatment in regard to this matter. He had in connexion with his own society found persons who had been examined by medical referees and declared to b permanently cured, and later the very same people had been paid off a permanently disabled, and they had not been able to work since There was no appeal from the medical referees, and Parliament ough to have the element of unfairness taken away by the appointment State-paid officials who would be able to devote their whole time to th work, and in whom the people would have confidence.

Mr. CHURCHILL (the Home Secretary) said that attention had bee called to the Workmen's Compensation Act, especially in regard to th appointment of medical referees. He was inclined to agree that th time was fast approaching when a committee of inquiry shoul investigate the conditions of the industry of the country with referenc to workmen's compensation. He had, therefore, given instruction to the Home Office, and the officials were now beginning to collec materials, and when those materials had been obtained he believe that the question would arise in a very practical form next yea When the committee reported the cycle of years would come roun again when special legislation on the subject could be intro duced. On the question of lead poisoning he quite agreed with th honourable Member (Mr. Hills) that although the number of cases wa small the evil was great and preventable to a very large extent, and was the duty of Parliament to exert itself to stamp it out altogether The Departmental Committee appointed in 1908, after a very thoroug investigation, made a report which was published last autumn, an that report had, on the whole, been well received by the trade. Som of the proposals in the report led to representations being made fro the manufacturers, and the Home Office thought that the best wa to deal with them would be to call the committee together to consult them again through their chairman, who had taken a immense amount of trouble, and the result was that a few modification of detail had been approved. Regulations following on the committee recommendations were about to be issued in draft. He was aske whether they would be ready for this debate, but they were in th last stage before they went to the printer. He thought that he ha said enough to show the House that on nearly all the lines whic had been referred to it the Home Office was moving steadil forward. On some matters action had been already taken, some ha reached the stage where action only awaited Parliamentary authorit and others had reached a point where a new inquiry was necessary, a in the case of the Workmen's Compensation Act; but on all these lines and without wasting time, the Home Office was doing its very best t bring the system of factory legislation abreast of, and in front of, th system of any other country in the world.

Mr. WEDGWOOD pointed out that lead poisoning was very serious i the coach-building trade as well as in the pottery trade. He wante regulations in the pottery trade for ensuring cleanliness in the sho and on the part of the workmen. Once places where lead processe took place were put under decent conditions there would be a state things which would go a long way towards eliminating lead poisonin in the potteries. By far the best way was to secure that the month examination should be thoroughly efficient. The people in the potte area were examined once a month by certifying surgeons. Thos certifying surgeons were not whole-time officials. They we medical men engaged in general practice, and they were paid f the examinations which they made by the manufacturers. The pa ments amounted in some cases to £700 a year. One medical man, was informed, examined as many as 1800 persons a month. Tho people filed in front of him. In these circumstances the examinati was nothing more than a farce. Both masters and men wanted to s these certifying surgeons whole-time officials, so that the examinati of the workpeople might be a really satisfactory examination whi would detect the first traces of lead poisoning and so prevent growth of it. The present position of the certifying surgeons w causing a great deal of discontent in the whole of North Staffordshi These gentlemen could not possibly do the work properly so long they had to engage in competition for other work.

Mr. JOHN WARD also spoke on the subject of lead poisoning, a said that it was desirable that the Home Secretary should announ when the suggestions made by the committee on lead poisoning we to be put into operation.

The vote was subsequently agreed to.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BRANWELL, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Fifth District by the Penzance Board of Guardians.

CASELLA, G., L. & L.M.R.C.P., L. & L.M.R.C.S. Irel., has been appointed Consulting Medical Officer to the Calamor Mining Company of Spain and to the Cordoba Copper Mines, Spain.

CASSIDY, MAURICE ALAN, M.D. Cantab., M.R.C.P. Lond., has been appointed Physician to Out-patients at St. Thomas's Hospital.

COOKE, EMILY SUSAN, M.B., B.S. Lond., has been appointed Assistant (Female) Medical Officer at the General Post Office.

DUTTON, H. DE B., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Banbury District of the county of Oxford.

EDGAR, T. BOWMAN, M.B., Ch.B. St. And., has been appointed Junior House Surgeon to the Dumfries and Galloway Infirmary.

FENWICK, CHARLES, L.R.C.P. & S. Edin., has been appointed District Medical Officer by the St. Thomas's (Exeter) Board of Guardians.

GIBBINS, FRANK, M.D., B.S. Lond., M.R.C.S., L.S.A., D.P.H., has been appointed Medical Officer for the Stithians District by the Redruth (Cornwall) Board of Guardians.

HOWARTH, WALTER G., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon-in-Charge of the Throat Department at St. Thomas's Hospital, and Surgeon-Laryngologist to the City of London Hospital for Diseases of the Chest, Victoria Park.

MACDONALD, JOHN FINLAY, M.D., Ch.B. Glasg., D.P.H. Camb., has been appointed Medical Officer of Health for the Auckland Rural District, county Durham.

MCELDOWNEY, W. P., M.B., B.Ch. R.U.I., has been appointed Honorary Physician to the Royal Portsmouth Hospital.

MACPHERSON, W. H., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Topsham District of the county of Devon.

MARTIN, ROBERT, L.R.C.P. & S. Edin., has been appointed Medical Officer to the Post Office at Banbridge, including Corbet, Edinordinary, Garvaghy, and Lenaderg.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN PROVINCIAL COMMITTEE FOR THE TRAINING OF TEACHERS.—Medical Officer and Lecturer on School and Personal Hygiene. Salary £400 per annum.

BARNSTAPLE, NORTH DEVON INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Locum Tenens. Salary 3 guineas per week, with board and lodging.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BURY INFIRMARY.—Senior House Surgeon. Salary £110 per annum, with board, residence, and washing.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—House Physician. Also Second House Surgeon. Salary in each case £80 per annum, with board, residence, and laundry.

CANCER HOSPITAL, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70 per annum.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon and House Physician, unmarried. Salaries £80 and £70 per annum respectively, with board, lodging, and washing.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with board, lodging, and washing.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £70 per annum, with board, apartments, and laundry.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing.

COUNTY OF LONDON.—Assistant Medical Officer (Education). Salary £500 per annum.

COVENTRY, CITY OF, SCHOOL CLINIC.—Part-time Oculist and Part-time X Ray Specialist. Also School Dentist. Salary £300 per annum.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

DARENTH ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary £30, with board, residence, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months, unmarried. Salary at rate of £50 per annum, with board, apartments, and laundry.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing.

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary £120 per annum, with board and lodging.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Salary at rate of £75 per annum, with board, residence, and laundry.

GLAMORGAN COUNTY COUNCIL.—Medical Officer. Salary £300 per annum.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.

HOLBORN UNION INFIRMARY, Archway-road, Upper Holloway, N.—Second Assistant Medical Officer. Salary £80 per annum, with board, apartments, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon and House Physician, both unmarried, for six months. Salary in each case £30, with board, residence, &c. Also Locum Tenens for Bacteriologist and Clinical Pathologist.

HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Assistant House Surgeon. Salary £40 per annum, with board and laundry.

KENT COUNTY COUNCIL.—Assistant to County Medical Officer of Health. Salary £300 per annum.

KIRKMABRECK, PARISH OF.—Medical Officer. Salary £40 per annum.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

LEICESTER INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, apartments, and washing.

LEICESTERSHIRE EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

LIVERPOOL INFIRMARY FOR CHILDREN.—Resident House Physician. Salary at rate of £60 per annum, with board and lodging.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £150 per annum, with residence and board.

LONDON HOSPITAL, E.—Six Honorary Dental Surgeons.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing.

MANCHESTER CHILDREN'S HOSPITAL, Gartside-street. — Assistant Medical Officer for six months. Salary £50 per annum.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Honorary Assistant Physician.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Surgeon and Assistant House Surgeon for six months. Salary at rate of £60 and £40 per annum respectively, with board and washing.
MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon. Salary at rate of £80 per annum, with board, attendance, and laundry.
MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—House Physician. Salary £75 per annum, with board, residence, and washing.
NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Professor of Physiology. Salary £450 per annum.
NORWICH, NORFOLK AND NORWICH HOSPITAL.—Two House Surgeons. Salary £80 each per annum. Also Casualty Officer, unmarried. Salary £60 per annum. All with board, lodging, and washing.
NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, &c.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.
PERTH, COUNTY AND CITY OF PERTH ROYAL INFIRMARY.—House Surgeon. Salary £60 per annum, with board.
PRESTON ROYAL INFIRMARY.—Junior House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Dental Surgeon.
ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Honorary Anæsthetist.
ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Surgeon.
SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.
SHEFFIELD ROYAL INFIRMARY.—Seventh Resident Medical Officer. Salary £60 per annum.
SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with rooms, board, and washing.
SWANSEA GENERAL AND EYE HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, washing, and attendance.
TAUNTON, SOMERSET AND BATH ASYLUM, Cotford.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, washing, &c.
TUNBRIDGE WELLS GENERAL HOSPITAL.—House Physician. Salary £100 per annum, with board, residence, &c.
WADSLEY, NEAR SHEFFIELD, WEST RIDING ASYLUM.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c.
WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Honorary Medical Officer.
WESTMINSTER HOSPITAL.—Resident Obstetric Assistant for six months. Board and lodging provided.
WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.
WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £80 per annum, with apartments, board, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Carnoustie, in the county of Forfar; at Malmesbury, in the county of Wilts; at Harwich, in the county of Essex; at Market Rasen, in the county of Lincoln; at Newburn, in the county of Northumberland; at South Shields, in the county of Durham; and at Wick, in the county of Caithness.

THE Secretary of State for the Home Department, Whitehall, S.W., gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for Bromsgrove, Redditch, and Droitwich County Courts.

Births, Marriages, and Deaths.

BIRTHS.

JUSTICE.—On June 22nd, at The Manor House, Marylebone, London, N.W., the wife of Captain W. A. Justice, I.M.S., Madras, of a son.
PAYNE.—On June 23rd, at Brunswick House, Kew, the wife of E. L. Payne, M.R.C.S., L.R.C.P., L.S.A., of a son.
ROSS.—On June 22nd, at The Grove Lodge, Sawbridgeworth, the wife of E. Athole Ross, M.D., M.R.C.P., of a son.
TOVEY.—On June 18th, at Kaponga, Taranaki, New Zealand, the wife of Arthur Hamilton Tovey, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

MARRIAGES.

CARLÉ—ELLIS.—On June 17th, at St. Jude's, S.W., Frederick Charles Carlé, M.B. Lond., M.R.C.S., to Elsie Maud, elder daughter of the late Henry Charles Ellis and Mrs. Ellis of Maidstone.
DICKSON—RICE.—On June 24th, at St. Michael's, Bowes Park, N., Robinson Simpson Dickson, M.D., to Marguerite Victoria, eldest daughter of W. G. Rice, Esq., J.P., of Grasmere, Bowes Park, N.
PRETTY—ELLIOT.—On June 17th, at Hampstead, Kenneth Pretty, M.B. Cantab., to Emily Hume, third daughter of the Rev. W. Hume Elliot, of Tooting Common.

DEATHS.

EMMERSON.—On June 22nd, at Guy's Hospital, London, John Bolton Emmerson, M.D. Durh., M.R.C.S. Eng., of Biggleswade, aged 57.
OSBORN.—On June 23rd, at St. Martin's-place, Dover, Ashby Greenough Osborn, M.R.C.S., L.S.A., in his 83rd year.
PLUNKETT O'FARRELL.—On June 22nd, at The Croft, Oxshott, from heart failure, Sir George Plunkett O'Farrell, Knt., M.D., aged 66 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"CARAVANNING" FOR HEALTH.

IN view of the importance that is more and more being attached to the open-air life, not only as a preventive, but even as a curative agent in the early stage of tuberculosis, there is a mode of attaining it which for ease, comfort, and convenience can hardly be excelled for those of limited means. All sorts of shelters have been devised, tent life has been recommended, devices for sleeping either entirely out of doors on roofs and balconies, or partly so with head out of window have been vaunted, yet the use of the simple caravan has not met with adequate encouragement from medical men. In "caravanning" is provided a means of outdoor life that is inexpensive in its preliminary outlay, costs ridiculously little in its working, enables one to seek solitude or company at will, permits of all degrees of enjoyment from mere comfort to absolute luxury according to one's means, and abolishes monotony by making frequent change of locality a possibility independent of income. The owner of a caravan can make arrangements with farmers and others in almost any part of the country for a "pitch" for his caravan at a cost varying from gratuitous "make yourself at home" up to some 5s. or 7s. 6d. a week the charges, when any are made, including grazing for the horse. As a "pitch" is usually secured near a farmhouse, arrangements can ordinarily be made for an ample supply of fresh milk and new-laid eggs—important items in everyone's bill of fare. For those compelled to go daily to town there should be little difficulty in securing a suitable "pitch" close to one of the railway lines that lead to London from all directions. Except in rainy weather and during the hours of sleep the caravanner usually spends all his time in the open; and even when compelled to be in his van there are means of rendering it freely open to the air, while preserving privacy and ensuring adequate warmth. During the Coronation week the Caravan Club of Great Britain and Ireland, which was founded in 1907 by Mr. J. Harris Stone, and now numbers 250 members, of whom two-thirds own their own caravans, held its annual meet in the beautiful country adjoining the London County Asylum at Cane Hill, Surrey, whose superintendent, Sir James M. Moody, is himself an enthusiastic caravanner. Some 15 vans of various kinds and sizes were assembled there, some having come from the farthest parts of England. Among them was the "Wanderer," the van of the late Dr. Gordon Stables, now inhabited by his widow and daughter. The commodious and serviceable van of Sir James Moody emphasised the æsthetic possibilities of caravanning, while various gipsy vans demonstrated what can be done to provide comfort from a slender purse. Vans can be bought from about £40 to a thousand guineas, to be drawn by horses or by motor power. Being moveable houses they are not taxable. Light portable tents, that can be attached to one side of the van, afford extra sleeping accommodation, or can be used as bathrooms; a very ingenious one, being really a sack, all in one piece, with waterproof floor, roof, sides, and ends, and opening only at one end, but adequately ventilated, was on exhibition. To the sportsman, the entomologist, the botanist, the artist, the photographer, the caravan offers an abundant source of inexpensive entertainment during the pleasant months of the year; but it is to those in search of health through the open-air life that we would especially commend caravanning. If any such will communicate (enclosing postage for reply) with Mr. J. Harris Stone, secretary of the Caravan Club, 358, Strand, London, W.C., they will be put in the way of obtaining all necessary information with regard to hiring, purchasing, building, or equipping of vans, approved "pitches" all over the country with expense thereof, and, in short, everything pertaining to caravanning.

PEDESTRIANS' PERILS.

IN these days of motor vehicles of all sorts, speeding along at 20 miles an hour, and very frequently at a much faster pace, and of aeroplanes and airships which may at an unexpected moment descend on a crowd of spectators with terrible results, or from which aviators may drop missiles, harmless or otherwise,—in these circumstances it would seem that the mere pedestrian, left behind, as it were, in these days of quick travel, will have to exercise extraordinary care or his safety will be seriously imperilled. It is astonishing, indeed, the risks the ordinary pedestrian is exposed to. The Steyning police court provides a case in point. A young motorist, Harold S. Powell, aged 19, accompanied by three friends, had a day's outing in a motor-car, proceeding from Storrington to Brighton. On the way defendant was seen driving the car with his left hand and firing a revolver with the other. In one instance water splashed up from a pond by a bullet went on a boy's face. Shots were also fired on the homeward journey. Through his counsel defendant said there was not the slightest intention of causing any harm or annoyance to anyone; that it was a

youthful freak. The bench, in fining the defendant £2 on each of three summonses for wantonly firing a pistol within 50 feet of the centre of the road—the offence being committed in three parishes—said the penalty was absolutely inadequate for such extraordinary conduct. They, however, marked their serious view of the case by mulcting one of Powell's companions in a fine of £7 10s. and costs for driving the car without a licence, while Powell indulged in his revolver practice on one part of the journey. It is all very well to be considered a good shot at Sandhurst, but to take a motor-car journey as an occasion for indulging in a little practice is much to be deprecated, and it is fortunate for young Powell and his companions too that no human being was struck by any of the bullets.

HOW THE LARCH SAW-FLY HAS BEEN KEPT UNDER AT THIRLMERE WATERWORKS.

SOME four or five years ago the larch saw-fly appeared in large numbers in the Lake District and for the most part was allowed to co tinue its ravages unchecked save in the Thirlmere district, from which Manchester draws such a large proportion of its water-supply. Naturally, this district, too, was invaded, and the larch plantations that had been set out by the Manchester corporation suffered heavily. Happily, however, the zoologists were able to suggest an effective remedy. Professor Hickson, of the University of Manchester, suggested that bird life should be encouraged on the estate, that the young larches should be hand picked to get rid of the flies, and that tarred tow should be wrapped round the stems. To encourage birds to settle on the estate round Thirlmere 250 nesting boxes were scientifically distributed in the trees, and of these 85 per cent. were occupied last year. This year 60 boxes have been added. The result has been that last year the saw-fly could hardly be found on the estate. The birds, especially the tits, eat up the caterpillars the moment they hatch, and in this way prevention proves to be better than cure. Care is taken to feed the birds during the winter. This is another good illustration of the usefulness of "economic entomology."

HEALTH AND CLIMATIC CONDITIONS OF RIO DE JANEIRO.

IT is stated in the annual report of Mr. Hamblock, the acting British Consul, that the population of the city of Rio de Janeiro, Brazil, is estimated at about 670,000 and of the surrounding suburbs at 200,000, thus making the total population of the federal district 870,000; the area is 1100 square kilometres. Rio continues to be free from yellow fever, though an isolated case was reported in the early part of 1911, but this was proved to be a case brought on a steamer from Bahia. Tuberculosis and diseases of the digestive organs are responsible for the majority of deaths in the district, while cases of "*grippe*" (a somewhat vaguely defined malady, probably influenza, but one which in its most serious form of "grippe intestinale" is said by some to be typhoid fever) are becoming more and more frequent. The summer was trying and the lack of rain abnormal. Farmers in the interior suffered considerably owing to the droughts, cattle died in great numbers, and many crops were ruined. The city was fortunately saved from what threatened to become a very serious shortage of water, but the scare has drawn the attention of the authorities to the many faults and conditions in the administration and control and *matériel* of the water-supply, and the matter is said to be receiving all possible consideration. In March, 1911, violent gales and torrential downpours of rain caused floods in all parts of Rio, communication was interrupted, and the lighting of the city suffered. The authorities are adopting measures to prevent, if possible, a repetition of this state of affairs, but the difficulties in the way are considerable owing to the peculiar position of the town, which receives tons of water from the surrounding hills, while means of egress for the water are few and quite inadequate. The birth-rate in 1910 was 27·79 per 1000 inhabitants and the death-rate 20·54 per 1000. There was an epidemic of measles from July to December. The deaths from "grippe" in 1910 numbered 678, as compared with 484 in 1909 and 481 in 1908. Tourists continue to come to Rio in increasing numbers, attracted by the extraordinary natural beauties of the place. The cost of living may, at a fair estimate, be considered about three times as high as in Europe.

HOSPITAL FLOORING.

THERE are various opinions with regard to the best kind of flooring for hospital wards. Many architects still use hard wood, such as maple, teak, oak, in very narrow widths like a ship's deck. Others use a form of flooring which is suitable either for laying on a board floor or a concrete floor. It is a German invention. The material is made up largely of sawdust and indurating substances, and it is put down in a plastic state, various forms of acid being used to harden it. "Dolomen" and "Terrano" are examples of it. A well-known architect informs us that he has come to the conclusion that the best form of floor is of concrete, finished with a smooth cement surface, and then covered with good linoleum stuck down solid all over. This is quiet and warm, and slightly elastic, and most easily cleaned. The "Terrazzo" paving, which is a sort of marble concrete rubbed down to expose the marble in a sort of rough tesselated pattern, is a very pretty form of flooring, but it is colder than "Dolomen" and not so elastic. It is rather unyielding to the feet, and the nurses sometimes complain of it, as they never do of linoleum. In all passages, corridors, and places where smartness is an asset, or where quick rough cleaning is necessary, such as sculleries, "Terrazzo" is the most suitable flooring. We are led to these remarks by the fact that several correspondents have recently asked us for advice upon the subject of flooring in connexion with the fitting of domestic buildings for hospitals and similar purposes.

IS LEPROSY TRANSMISSIBLE?

"THE answer is in the negative," according to Dr. G. Photeinos, professor of dermatology in the University of Athens and director of the Hospital for Contagious Diseases in the same seat of learning. Leprosy has of late numbered many cases in the Island of Crete, particularly at Spinalonga, and Professor Photeinos, just returned from a prolonged visit to the locality, has, as the result of bacteriological and clinical research, been constrained to agree with the Cretan physicians that not even by inoculation can the disease be transmitted from the leprous to the non-leprous subject. Of his *catena* of cases the most striking is that of a young woman who, finding her husband to have been officially declared a leper and grieved beyond measure at the prospect of being separated from him, seized a knife, made a deep incised wound on her person, and squeezed into it a quantity of the virus from the sores of the said husband who was standing near. "Now," she exclaimed, "I too am a leprous subject and entitled to remain with my husband." The two were accordingly sent together to Learocori (the leper village), and there the devoted wife, spared from the disease, continued for 15 years to take care o her husband and of the other patients, showing herself to be an excellent and assiduous nurse. Her husband is now dead, but the widow, still immune, remains in the village, wedded to her self-imposed *métier*.

HOSPITALS IN BASUTOLAND.

Mr. H. C. Sloley, the British Resident Commissioner in Basutoland, in his annual report just received at the Colonial Office, mentions that new hospitals have been opened at Mafeteng and Mohale's Hoek during the year. Another small hospital has been completed at Moyeni, in Quthing District, but not yet opened. Maseru Hospital has been enlarged to accommodate 40 beds. The work done in the public dispensaries is most gratifying, a total of 37,000 cases having been treated during the year. The question of leprosy, which has been drawing attention all over South Africa, is being studied in Basutoland also.

TUBERCULINS.

"TUBERCULINS and their Employment in Diagnosis and Treatment of Tuberculosis" is the title of a pamphlet issued by Meister Lucius and Brüning, in which, after a brief *résumé* of the details of Koch's researches for a non-toxic immunising agent derived from the tubercle bacillus, they describe the various tubercle preparations now put upon the market, dividing them into three classes: (1) Preparations obtained from broth containing tubercle bacilli; (2) preparations obtained from germ-free tubercle bacilli bouillon; (3) preparations from free tubercle bacilli. A section on the diagnosis of tuberculosis follows, which describes the methods of subcutaneous injection, the cutaneous reaction, the percutaneous inunction method, and the conjunctival reaction. The clinical results of diagnostic tuberculin tests and the employment of tuberculins for the cure of human tuberculosis are pointed out. The pamphlet will be sent gratis to physicians on application to the publishers, 51, St. Mary Axe, London, E.C.

L. C.—There is a good description of the Plombières baths and waters in "Crénotherapie, Climatothérapie," &c., par le Professeur L. Landouzy and others, published by J. B. Baillière et Fils, 19, Rue Hautefeuille, Paris. 1910. Price is something between 8 and 12 francs. Pages referring to Plombières 384–396. Dr. William Bain and Dr. Wilfrid Edgecombe also mentioned it in their book, "The Physiology and Therapeutics of the Harrogate Waters," published by Longmans in 1905, and the Plombières treatment has been carried into practice at Harrogate since then.

Dr. W. H. Bishop.—"The Ship's Surgeon's Handbook," by A. V. Elder is published by Baillière, Tindall, and Cox, at 5*s.* net.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for July and August, 1911:—

April-October.—Rome Exhibition (United Italy's Jubilee).
,, 29th-Oct. 26th (Turin).—International Exhibition.
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.

May 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
,, 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
,, 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
June 1st–August 31st (Squirrels Heath, Romford).—Town Planning and Modern House and Cottage Exhibition.
July 3rd–5th (Bergen).—Seventh Norwegian Congress of Internal Medicine.
,, 6th and 7th (London).—Imperial Health Congress.
,, 13th and 14th (Oxford).—Oxford Ophthalmological Congress.
,, 24th–27th (Portsmouth).—British Pharmaceutical Conference.
,, 24th–28th (London).—Second International Congress of Urology.
,, 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
,, 25th–28th (Birmingham).—British Medical Association, Seventy-ninth Annual Meeting.
,, 26th (Rouen).—French National Dental Congress.
,, 26th–29th (London).—Universal Races Congress.
,, 31st–Aug. 4th (Paris).—Second French Congress of Stomatology.
,, 31st–August 5th (Dijon).—Congress of the French Association for the Advancement of Sciences.
August 1st–6th (Amiens).—Twenty-first French Congress of Alienists and Neurologists.
,, 3rd–5th (London).—British Dental Association, Annual Meeting.
,, 12th–18th (Brussels).—First International Congress on Child Study.
,, 12th–30th.—E.M.I. (Enseignement Médico-mutuel International) Tour in Scandinavia.
,, 15th–21st (Dublin).—Royal Institute of Public Health.
,, 21st–23rd (Larvik).—Fourteenth Norwegian Physicians' Congress.
,, 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Études Médicales."
,, 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th–Sept. 6th (Portsmouth).—British Association.
,, 31st and Sept. 1st (Vancouver).—Thirteenth Annual Meeting of the British Columbia Medical Association.
,, (Carmarthen).—Welsh National Eisteddfod.
Sept. 4th–9th (Yarmouth).—Sanitary Inspectors' Association. Annual Conference.
,, 5th–7th (Philadelphia).—American Electro-therapeutic Association.
,, 9th–11th (Ostend).—Fifteenth Flemish Nature and Medical Congress.
,, 11th–13th (Vienna).—German Urological Society.
,, 11th–15th (Berlin).—Third International Conference on Infantile Mortality (*Gouttes de Lait*).
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.
,, 12th–15th.—Celebration of the 500th Anniversary of the Foundation of the University of St. Andrews.
,, 18th–23rd (Rome) Seventh International Congress of Dermatology and Syphilology.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—G. F. Blacker, J. H. Targett), at 11, Chandos-street, W.: at 8 P.M.

Specimens:
Dr. V. Bonney: An Aid in the Diagnosis of Carcinoma.
Mrs. Scharlieb, M.D.: (1) Adeno-carcinoma of Ovaries and Uterus; (2) Carcinoma of the Rectum.

Address by the President (Dr. Macnaughton-Jones):
The Appendix—its Relation to the Causation and Surgical Treatment of Affections of the Adnexa.

FRIDAY.

ANNUAL GENERAL MEETING OF FELLOWS at 5 P.M.
Election of Officers and Council for Session 1911–1912.

SATURDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—J. P. Lockhart Mummery, T. R. Whipham, G. S. Haynes)

Provincial Meeting at Cambridge.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 2, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Mr. R. E. Bickerton: Ocular Malingering and its Detection.

TUESDAY.—4 P.M., Dr. J. Collier: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. S. R. Russell: The Diagnosis of Intracranial Tumours (with lantern demonstrations).

WEDNESDAY.—4 P.M., Mr. G. E. Waugh: Clinique (Surgical). 5.15 P.M., Lecture: Dr. A. E. Giles: Malformations in their Clinical Aspects.

THURSDAY.—4 P.M., Mr. H. S. Clogg: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. G. R. Turner: The Modern Treatment of Hernia.

FRIDAY.—4 P.M., Mr. K. Campbell: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Ll. Williams: The Extraction of Teeth, When and How.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Intestinal Obstruction from Medical Point of View.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture V.)

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. G. Stewart: Intracranial Tumours.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, are given in this issue of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Lumleian Lectures

ON

A CLINICAL STUDY OF CARDIO-VASCULAR DEGENERATION.

Delivered before the Royal College of Physicians of London

BY J. MITCHELL BRUCE, M.A., LL.D. HON. ABERD., M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON THE PRACTICE OF MEDICINE AT, AND CONSULTING PHYSICIAN TO, CHARING CROSS HOSPITAL, ETC.

LECTURE I.

Delivered on March 23rd.

INTRODUCTION.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—I desire to convey my best thanks to you, Sir, and to the Censors' Board for having honoured me by appointing me to fill this ancient and honourable office in the present year, and to commemorate with you the devotion and liberality of Dr. Richard Caldwell and Lord Lumley to the College. As well as the distinction that attaches to it, another consideration moved me to accept your invitation. I felt that the discharge of the duty which it involves would afford me an occasion to unburthen my conscience of a sense of neglected opportunities. One who realises that he is numbered among the seniors of the College necessarily has at his service for such a purpose as the present many records of cases, as well as that less determinate possession called "experience," which ought to be turned to some use, but which without special stimulus would lie neglected and finally be lost. My selection of the subject of cardio-vascular degeneration in particular was prompted by the possession of a considerable amount of clinical material bearing upon it. Let me add, by way of further apology, that whilst an examination of records that have been accumulating for years is itself a heavy undertaking, a study of degeneration of the heart and arteries involves so many forms of knowledge, pathological as well as clinical, and what knowledge we may possess of human nature as well as of the nature of life and death themselves, that one presently feels overwhelmed by the difficulties of the task, and astonished at one's temerity in undertaking it. I can only say that, whatever may be the value of this study, it was approached and pursued with an open mind—without prejudice for any one of the many and diverse doctrines on the pathogenesis of arterial sclerosis and of senile changes in the heart.

The presentation of my results will be entirely unsystematic. It will be no methodical and complete description of the clinical characters of cardio-vascular degeneration, but will consist of the results of an examination of various portions of the subject that have a distinct bearing on practice—that is, on prognosis and treatment. The title, and my definition of it, must therefore be accepted as elastic. I shall not attempt to draw a line between degeneration and chronic inflammation, between atheroma and chronic aortitis. Whilst I shall have much to say about syphilis of the aorta and heart, I shall make but passing references to aneurysm, and to syphilis—or indeed other diseases—of the cerebral arteries, or to rheumatism as a precedent of degeneration. Nor does time permit me to discuss—if I could discuss it with any profit to medicine at the present time—the vast clinical and pathological problem of chronic Bright's disease in its relations to cardio-vascular degeneration, and the part played in it by that influence of evil significance, high blood pressure, which cannot be satisfactorily accounted for by our present knowledge, and which as to its nature or origin constitutes the unknown quantity, the mysterious x, that is being sought with so much industry by observers at this moment.

I need not dwell on the importance of this subject. According to the report of the Registrar-General for 1908 the mortality from cerebral hæmorrhage in this country in persons over 35 years of age is 2·083 in a million men and 2·284 in a million women. It would appear that many lives are lost from arterial disease at an age when work ought to be still carried on in the interests of the family and the country, at an age when a man's reasonable ambitions, as a rule, have not yet been attained.

DURATION OF LIFE.

We must be content with limitation of life. Death is natural, for it is universal—individual death. But equally natural and universal is the desire to make death remote. To attain the maximum age has been a subject of unbroken interest and effort in the history of the world: to lengthen the span of a healthy, peaceful, unclouded old age. Now the natural age of man is not three score years and ten. That age may be the ordinary maximum; but the natural limit of life is the greatest age that has been reached according to authentic records. And why should not life be interminable? This is a vain question, interesting as was the discussion of it by Sir William Allchin in his oration on "The Breaking Strain." But it serves to suggest another question—one of the questions that inspired my present study. What is the origin, the meaning of this process of degeneration of the cardio-vascular system that is completed in death; and why should its fatal effects be met with so often before their time? I will refer but briefly to the first part of this question—the meaning, the general pathology, of degeneration as it affects the heart and arteries, for I must hasten to the examination of the second part of the question—how it comes to be premature—in the hope of finding an answer to it that may have some useful application.

CAUSATION OF CARDIO VASCULAR DEGENERATION.

I would only remind you that life consists in the actions of the countless influences that fall upon the body, and the reactions of the body to them, and that the state of our organs as we find it is the result. The process of wearing-out of the organs of circulation, characterised anatomically by degenerations of different kinds, is a manifestation of this vital process in individuals who have escaped death from the diseases and accidents of earlier life. Regarded comprehensively, the environment, including the pathogenetic influences (so called, but quite indeterminately limited), acts on the heart and arteries in two directions. First, it affects the nutrition of their walls. This is disordered, and may be ruined, by poisons, inorganic and organic, including lead, alcohol, and the products of bacterial activity; by micro-organisms themselves; by the products and other consequences of disordered metabolism; by the spirochæte of syphilis, and by other parasites. No doubt there are also dystrophies of the heart and arteries of nervous origin, central and reflex. And we may perhaps be permitted to assume for the present that simple length of use of the elements of the vascular and cardiac walls may finally wear them out. In constant opposition to these pathogenetic influences on the cardio-vascular tissues are natural provisions for maintaining their nutritive soundness and physiological efficiency. The endocardium and the intima are nourished by the circulating blood in which they are bathed. The vasa cordis and vasa vasorum supply the other structures; and their associated veins and lymphatics provide for elimination. The nervous system affords wholesome impulses which serve to control the processes in favour of health. In the majority of individuals these provisions are sufficient, and continue so for what we are pleased to regard as the natural "expectation" of life.

Thus abundantly provided or protected against the morbific influences which threaten the substance of their walls, how come the heart and arteries to fall victims to them so early in some individuals, sooner or later in all? Vitality fails here, as elsewhere in the body, from either side—from very severity of the essential cause, or from insufficiency of natural resistance—or it fails from both sides together.

How many and powerful the extrinsic elements of the causation of cardio-vascular degeneration are we shall see presently. But of equal etiological importance with the violence or persistence of these is relative insufficiency of the provisions for meeting them. In a small proportion of individuals the materials of the cardiac and arterial tissues are essentially inferior in quality. This is one of the instances of inherited dystrophies—in part the "family heart." But there is another consideration that concerns all individuals. The nutrition of the cardiac and vascular walls is automatic. Now the obvious advantages in this arrangement are secured at the cost of its being self-dependent, which involves a grave risk if disorder or disease arise. The heart and vessels that circulate the blood are fed by the blood—that is, ultimately

by themselves. The blood depends on the vessels for the provision of its own constituents, regeneration and purification. The vasa that supply the heart and arteries are dependent for their own nutrition on the activities and soundness of these. Self-dependence of the circulation, and mutual dependence of its elements of this character, favour the development and extension of vicious circles of malnutrition once disability or damage occurs in any part of the system. Might one venture to speculate that here one finds a reasonable explanation of "wear and tear," the necessary or natural degeneration of the cardio-vascular system and its dependencies?

THE PART PLAYED BY INTERNAL PRESSURE.

The second direction in which the environment influences the organs of circulation is through internal pressure. Whether it acts on the circulation as a whole or only on a portion or a region of it, whether it is in the form of physical stress or of nervous origin, or an effect of specific poisons like lead, or of excess of blood, or of the quality of the blood, or of disturbance of respiration or of excretion, and whether the pressure be directly central (cardiac) in its source or directly peripheral, high blood pressure would strain the walls from within were it not opposed by another set of natural provisions. These are, first and most obvious, the passive resistance, the material "strength" of the parietal tissues, the fibrous structures of the adventitia and the pericardium. Secondly, there is the property of extensibility with associated elasticity possessed by the elastic elements of the vascular walls, which not only prevents shock and permanent dilatation and rupture by receiving and momentarily storing energy, but positively promotes the circulation by liberating it again. Thirdly, there is the function of reaction possessed by the muscular elements, which regulate the local pressures and the blood-flow in organs in response to their metabolic activity and maintain the general tone of the circulation. And, lastly, there are the other physiological mechanisms resident in the circulation and its nervous connexions: the myogenic and neurogenic mechanisms of the heart, the vagus and sympathetic supplies to the heart, and the vaso-motor and vaso-dilator supplies to the arteries.

These physiological provisions against the effects of high internal pressure also are exercised at the risk of disablement, automatically developed and automatically increased. Undue exercise of them, in degree or in time, provokes hypertrophy of the muscular elements and an over-growth of the fibrous and elastic tissues, which is entirely conservative or compensatory in its significance—the defensive replacement, or "strain-hypertrophy" of Adami. But the resulting thickening of the wall and narrowing of the lumen from sclerosis and hypermyotrophy increase the stress on the internal surface of the vessel, provoke in turn a further rise of pressure, and establish the necessary conditions of a second vicious circle leading from bad to worse, from fibrous to fatty degeneration—wear and tear in another fashion.

The ultimate result of these actions and reactions between environment and circulation is unfavourable to the circulation. The hypertrophied and fibrosed walls of heart and vessels, though they be hypertrophied and fibrosed as the results of genuine physiological reaction and anatomical repair, are less and less sufficiently nourished, and now yield to the high pressure that the thickening has provoked. Whilst the pathogenetic influences continue, and, indeed, necessarily increase with age, resistance is steadily reduced. The issue can be but in one direction—degeneration with disablement, which ends in death. It appears that damage of the circulation, however small to begin with, necessarily grows and spreads. If we are to delay the fatal issue, to prolong life, to reduce the number of premature deaths from cardio-vascular degeneration, we must work in two directions. On the one hand, we must promote those provisions for resistance, reaction and repair which the circulation possesses so abundantly; on the other hand, we must laboriously seek out the influences that can be proved to damage it, study the manner of their incidence and of their actions, and attempt to anticipate or counteract them. As Professor Humphry said many years ago in his work on Old Age"[1]: "The first requisite for longevity must clearly be the inherent or inborn quality of endurance; of steady, persistent nutritive force, which includes reparatory force and resistance of disturbing effects; and a good proportion or balance between the several organs. The second requisite is freedom from exposure to the various casualties, indiscretions, and other causes of disease to which illness and early death are so much due."

[1] Old Age, pp. 11 and 12.

HIGH ARTERIAL TENSION AND SCLEROSIS.

At the present moment a great body of clinicians and pathologists all the world over are laboriously investigating the problems connected with the blood pressure and the histology of sclerosis and atheroma and the associated changes in the heart. Until these problems have been solved we cannot hope to prolong life, to prevent or remedy premature degeneration. But so much work has been done in these directions that the attention of the profession at the present time may be said to be almost confined to the two conditions—arterial tension as it is estimated instrumentally, and arterial sclerosis. The very attractiveness of the newer methods of investigating the character of the pulse, and the readiness with which thickening of the radial artery can be determined, are unfortunate in this respect—that they encourage incomplete diagnosis. I need not say to you, Sir, and to this learned audience, that something more than "high arterial tension" and "arterial sclerosis" must be reached in the way of a diagnosis in individual instances—if by diagnosis we understand a conclusion on which we are to base prognosis and treatment. The cause, the nature of the pathological process, of which high tension and sclerosis after all are but evidences, must be determined if possible in every case of the kind.

CLINICAL INQUIRY INTO THE ORIGIN OF THE MORBID PROCESSES.

My own work, purely clinical in its character, and involving in every case a definite expression of opinion in respect of prognosis, has necessarily included an inquiry into the origin and beginnings of these conditions of disorder and disease. I confess that I have found it a difficult proceeding to attempt to discover the causes and trace the earliest phases of the morbid processes that end in arterial sclerosis and atheroma and in degeneration of the valves and walls of the heart. A man of 50 comes to us for our opinion and advice. He has lately become conscious of shortness of breath on moderate exertion, of præcordial oppression, possibly of pain across the sternum, extending into one or both arms, on walking to business after breakfast. He suggests that his stomach or liver is out of order, but he obviously suspects that his heart is concerned in the production of the discomfort. Or, instead of such symptoms, the man's complaint is of nothing more serious on the surface than vertigo or insomnia, or rheumatism (as he calls it), or eczema, or of a sense of unfitness for work and fits of depression. These statements and our patient's appearance and age suggest to us that his circulation is either disordered or actually diseased. We find his radial sclerosed, the heart enlarged, with a somewhat diffused shock representing the impulse, and a systolic murmur over the aortic area. The diagnosis is obvious: the man is the subject of arterial degeneration and its effects as far as they have developed. If we were to proceed forthwith to give this man our opinion and advice we should find that we do not possess either the elements necessary for prognosis, or the indications necessary for treatment. To obtain these we must make close inquiry into the patient's whole history, particularly with respect to his occupation and habits, the diseases from which he had already suffered, his constitutional strength and physical training and disposition in earlier years, and, more remote than these, his inheritance. Our purpose is to discover if possible which element or elements in the long chain of events and conditions that have constituted our patient's life may have been, either by excess or by default, responsible for the disorder or disease that has now overtaken him. Experience and our knowledge of the accepted causes of cardio-vascular degeneration enable us to limit these inquiries within moderate bounds. We ask after liability in the family to cardiac disease, and to gout, diabetes and gravel; after the use or possible abuse of athletics in youth; after the acute infectious diseases from which he may have suffered, never forgetting syphilis; after the amount of physical stress and nervous stress involved in his professional, business, or private concerns; and we go

into the details of his indulgence in food, alcohol and tobacco, and his enjoyment of wholesome exercise.

It is laborious, this inquiry into the family history and past personal history of each patient. And I confess that the information one receives in reply is often indefinite and misleading, for example, with respect to gout as distinguished from rheumatism. Sometimes the truth is wilfully concealed, particularly as regards syphilis. Important facts like albuminuria and glycosuria are usually unknown to the patient. The etiological value of certain influences, such as nervous stress, cannot be estimated quantitatively. And, finally, the causation may be so multiple and complex that one cannot disentangle the elements of it—toxic, physical and nervous—and apportion to each its proper share in the production of the disease.

DIFFERENTIAL DIAGNOSIS OF VARIOUS CLINICAL TYPES.

Difficulties like these tempt us to be content with less than the truth, with results unsatisfactory to us as naturalists, and comparatively useless for the purposes of prognosis and treatment in the interests of the patients. I therefore asked myself whether it might not be possible to differentiate the various kinds of arterial sclerosis and cardiac degeneration by their clinical characters. Does each kind of these diseases, according as it is known to be produced—e.g., by syphilis, physical stress, alcohol, and the rest—possess some signs and symptoms so relatively characteristic as to be diagnostic of it, or at least to suggest the etiological diagnosis and indicate the direction in which closer inquiry should be pursued? And, further, are these characteristics of each kind or type sufficiently marked to enable the observer to recognise the respective effects of associated causes—for instance, of syphilis and glycosuria—when they come together in an individual instance?

This consideration suggested to me one direction that such a study as the present might usefully take, and I determined to follow it. I am hopeful that you may allow that the result of my inquiry, which I will now submit to you, does support the correctness of my anticipation that there are different clinical types corresponding with different kinds of cardio-vascular degeneration, which can be and ought to be differentially diagnosed, and that in some instances at least of complex causation they can be disentangled and the respective elements at least duly appreciated.

RELATIVE FREQUENCY OF CAUSES.

But first let me tell you what I have found to be the relative frequency as causes of cardio-vascular degeneration of the influences in our every-day life that are generally accepted as producing it. For the present I will not attempt to classify them nor to suggest in which of the several possible ways they produce or promote degeneration.

In 100 cases of cardio-vascular degeneration taken casually from my records (92 of them men of the average age of 58½ years, eight of them women of the average age of 63½ years, at the date of observation) there was a history of syphilis in no less than 26. Acute febrile processes of extrinsic origin—due to micro-organisms or their toxins (which attack the arterial intima as they attack the endocardium)—are difficult to reckon statistically, for one or other of them has been at work in every individual who has reached middle age. Fifty per cent. in my series had had influenza, typhoid fever, acute pneumonia, or other disease of this order.

A group of universally accepted causes are the disorders of assimilation and metabolism; and of these glycosuria was present in 15 per cent., and gout in no less than 44 per cent. This group of causes brings arterio-sclerosis and cardiac degeneration into further etiological relations—with over-eating, with excessive indulgence in certain elements of food, with insufficient exercise, and still more remotely with nervous depression and habits that provoke indigestion, constipation and malassimilation.

In 31 per cent. of my series I obtained a history of either free or excessive indulgence in alcohol. Tobacco, an exceedingly common cause of cardiac disorder (in rare instances, indeed, of death through the heart), does not, in my experience, produce either enlargement of the heart or thickening of the arteries, and but for its incidental effect on a circulation enfeebled by degeneration of other origin it might be ruled out of the list.

I referred a few minutes ago to the influences of an entirely different class—the dynamic—that fall upon the organs of circulation and damage them when excessive more particularly in middle and advanced life. These are the stresses of a physical kind. Muscular exertion, in laborious occupations, in sport, or by accident, was present in 19 per cent. of the cases in my present series, no doubt usually associated with other possible causes. Allied to the physical stress of muscular effort, but different in being continuous and far more grave in its effects on the circulation, is that form of high intra-cardiac and intra-vascular pressure which goes by the name of "arterial tension." This is a common accompaniment of the causes I have already named, because an effect of some of them, and, as we have just seen, an effect of the sclerosis of arteries and viscera produced by some of them, alcohol especially. I shall be excused from attempting to name a figure of percentage-frequency under this head and that of granular kidney, which, as I have already said, I have excluded from my series.

Almost as difficult is it to satisfy oneself in an inquiry of this description how far nervous stress may be reasonably charged with the production of arterial sclerosis and disease of the heart. I shall return to this question at the proper time; but meanwhile let me say that the great majority of the 100 cases which I analysed for etiological purposes were men working with their heads rather than with their hands, and that in 31 of them such work involved directly or incidentally worry and anxiety sufficient to constitute a complaint.

It will have been gathered from these percentages that in many instances two or more accepted causes fell together; and, as I have said, one of the interests in the study, and one of my objects in the preparation of this communication, was to attempt to distinguish them.

CASES DUE TO "WEAR AND TEAR."

One other point I would discuss here in taking leave of the subject of causation in general. In a small number of instances of cardio-vascular degeneration not one of these influences which I have called its "recognised" causes was found to be, or to have been, at work, unless it were an infective fever. The majority of such subjects were of advanced age, but others had not reached 60. How had their circulation given way? The character of their symptoms and the course of their cases were not those which we connect with the unknown x. It is these cases that I would label "wear and tear." Sir Clifford Allbutt appears to employ this name as synonymous with mechanical stress. Perhaps he would not object to my using it in a more comprehensive sense—to cover "the thousand natural shocks that flesh is heir to," psychical as well as physical. Sooner or later every individual who has escaped greater, irresistible shocks—mechanical injuries, poisons, virulent infections and the rest—yields to the forces around him. Not a single overwhelming event nor several severe attacks, but a series of small, insidious, mostly unperceived actions upon his circulation, of an unfavourable character, as numerous as his own days, make physiological response to the circumstances of life ultimately an impossibility. This is what I would call wear and tear.

The pathological anatomy of this type of case, which appears to correspond with Sir Clifford Allbutt's "decrescent" or "involutionary" form, has been very closely studied during recent years, particularly in America, by several observers, under the inspiring influence and example of our distinguished Member, Professor Adami. They have described to us the manner in which the effects of wear and tear of ordinary life are represented by changes in the different elements of the cardiac and vascular walls. No doubt in some of these instances a family disposition or predisposition can be traced. But let me hasten to add that neither in this connexion nor in any other connexion is inheritance to be reckoned amongst the causes of degeneration. Inheritance concerns the resistance of tissues to the influence of disease; and family proclivity plays its part in the production of cardio-vascular degeneration, not as an essential cause, but as a defect in the provisions for resistance, a defect either in the material or in the mechanism of the organs of circulation.

I will now take up the generally accepted causes of degeneration of the heart and arteries in an order that favours their differentiation, beginning with syphilis.

SYPHILIS.

There are obvious advantages in the selection of syphilis as the first of the recognised causes of cardio-vascular

degeneration to be studied in our present connexion. Syphilis is one of the most common of causes that we have found, occurring as it does in 26 of my 100 cases. It is definitely specific in its nature—that is, due to an extrinsic parasitic influence of known characters. And further, we have no difficulty in finding cases of cardio-vascular disease in which it is the only cause that can be reasonably accepted. For these reasons syphilis is of all the causes of cardio-vascular disease the one that might be expected to present characteristic clinical features and a characteristic course, and to be capable of being identified by its effects even when associated with other causes. How far this is the case will be gathered from a summary of the results of a clinical study of 70 odd cases which I collected and analysed.

FIRST MANIFESTATIONS.

In this series the first manifestations of syphilis at the root of the aorta and in the heart occurred at the average age of 49, 25 years (again on an average) after the primary infection, with a maximum interval of 54 years and a minimum of five years. It is a question of practical interest to us what the condition of the root of the aorta may have been in these cases in the interval between primary infection and the earliest local symptoms. It is highly probable that in spite of its latency clinically—that is, the absence of symptoms—syphilitic aortitis has existed and been slowly progressing in area for years before it declares itself unmistakeably to the patient and the clinical observer. The proper age of aneurysm of the aorta—"the prime," as Sir Clifford Allbutt says, "when muscular stress and syphilis work together"—practically proves this. At the later age which my patients had reached the evidences of syphilitic invasion of the aortic root and the cardiac valves were developed so gradually in the majority of instances—as a rule in the form of presternal oppression on exertion—as to support the same view. When symptoms were suddenly developed, as they were in a few instances, it was clear that they were symptoms of fresh or further damage of already diseased structures.

Thus a retired soldier of 71, with a remote specific history, was suddenly seized with pain in the sternum and at both elbows in stooping to lace his boots. Although he had felt and believed himself to be sound, he proved to have dulness over the manubrium, an aortic systolic murmur, and tortuous thickened radials; and he continued to suffer pain for days, even in bed. No doubt sudden movement and interference with respiration in the stooping posture strained a small area of the arch that had long been diseased. A man of 51, who had had syphilis as a lad and no manifestation of its activity in the interval, was suddenly taken with pain over the manubrium and down the left arm, accompanied by faintness, at the end of a hearty luncheon with brandy and cigars. The pain, once begun, continued to be so severe as to demand repeated doses of morphine, and when I saw him within three weeks of the attack I found a double aortic murmur. And I have known the first manifestation of syphilis of the centre of the circulation to be sudden cardiac failure threatening dissolution, consequent on careless living. Probably sudden death from this disease, so frequent a manner of its termination, may be the first evidence of its existence in some instances.

Notwithstanding such proofs of the existence of syphilis in the walls of the aorta, the length of the average interval that I have named between infection and the first symptoms—25 years—proves sufficiently that the disease is in great measure successfully controlled by the nutritional vigour of the blood and tissues, ready, no doubt, to assert its existence and activity if the general health be lowered or the invaded parts be damaged. Have we any evidence as to the nature of the change that may be developed in the patient's condition or of the incident that may occur to lower the vigour of the local provisions for nutrition that have restrained and localised the action of the spirochæte for 25 years? Almost necessarily it is a cause that is not efficient in earlier years like physical stress; it must be some influence that comes into play about the age of 45 or 50, associated with the habits, concerns and circumstances generally of middle age, and the effect of these on the activity of the processes of general metabolism. I made careful inquiry on this subject in a number of my patients. I found a history of free indulgence in alcohol in 36 per cent. of them, of gout in 27·5 per cent., while 30 per cent. had albuminuria, and 2·5 per cent. glycosuria. To these unfavourable influences have to be added other causes of reduced tissue-resistance that so often characterise middle life, including nervous disturbance in the forms of worry, anxiety and misfortune. In only 10 per cent. of my cases was there evidence of physical stress.

It may occur to some of my hearers that the causes other than syphilis which I have just named as contributory or precipitating, not syphilis itself, ought to be credited with the production of the lesions in the aorta and heart. I hope to prove to you in my next lecture that the pathological effects of alcohol and gout and glycosuria and nervous stress on the vascular and cardiac tissues are so different anatomically from those of syphilis that their true etiological relations cannot be mistaken. The bearing of these facts upon the prognosis and general treatment of syphilitic subjects will be dealt with later on.

SYMPTOMS AND SIGNS.

Coming now to the symptoms and signs of syphilis of the cardio-vascular system as far as the present study extends, let me say at once that they were mainly those which characterise affections of the arch and root of the aorta, including the coronaries and the semilunar valves but excluding aneurysm. Pain was the prominent complaint in more than one-half of the cases (60 per cent.). It was anginal in 30 per cent., præcordial in 30 per cent. Dyspnœa was also complained of in 60 per cent., and palpitation in 57·5 per cent.; faintness or actual faints in 45 per cent.; præcordial oppression in 10 per cent. Cerebral disturbances and other less direct symptoms were variously mentioned.

Of all kinds of cardio-vascular degeneration syphilis presents the most obviously morbid signs on physical examination. In half of my cases I found a systolic murmur over the root of the aorta, more or less well marked; and in no less than 60 per cent. of the same cases an aortic diastolic murmur. Whether with or without a diastolic murmur the second aortic sound was loud and ringing in nearly one-third of the patients. On the other hand, an apical systolic murmur was heard in only one-tenth of all the cases; and in one-half of these it was imperfectly developed. This is a point to which I desire to draw your particular attention as of diagnostic value.

The other physical signs connected with the heart and aortic arch may be said to correspond with those described. In one-third of the cases there was presternal dulness, and in a small proportion mediastinal crepitations. The præcordial dulness and impulse significant of hypertrophy and dilatation of the heart were not always as well marked as one finds in aortic lesions of rheumatic origin; but it must be remembered that patients suffering from cardio-vascular degeneration in the fifth decade commonly have some degree of emphysema and rigidity of the chest which interfere both with palpation and with percussion.

Is there anything in the pulse and other features of the radial artery that can be said to characterise syphilis? Certainly they are not exactly such as we might at first anticipate in one respect—namely, evidences of sclerosis. In more than one-third of my cases the walls were not thickened; and Corrigan's pulse was relatively rare. These characters of the radial artery are another evidence of a fact on which I wish to insist: that syphilis of the organs of circulation is a locally distributed disease; that the radial may be free whilst the aorta is involved; and that clinical evidence to this effect may be sufficient to enable us to diagnose it even if infection be denied by the patient, or if it be associated with one or more other causes. This clinical observation is confirmed by pathological results. Huchard says that syphilis has no great tendency to be generalised, and is more often circumscribed—limited to one or several vessels. Dr. Mott agrees with this statement.

Another conclusion would appear to follow from the soundness of the radial in so many instances of syphilis. The aortic valvular lesions cannot well be of such degree to disturb the pressure greatly in the peripheral arteries, and in accordance with this conclusion is my observation that the diastolic aortic murmur and—as I have just said—the præcordial impulse are often weak. Other interesting features of the pulse in this disease are its regularity (80 per cent.), considering the severity of the lesions and the age of the patients, and the absence of intermittency. That the

diastolic pressure should be low or moderate in 75 per cent. of cases follows from the frequency of aortic incompetence.

If we now review the clinical characters of this group of cases I believe you will agree with me that they constitute a body of evidence which may substantially serve to differentiate syphilis from other causes of the disease. But you may not be prepared to do so until the character of the other groups have been submitted to your attention and judgment

CLINICAL COURSE.

The clinical course of syphilis of the root of the aorta and heart (excluding aneurysm) is more often slow, but life throughout is entirely insecure, and the duration of the disease when it has become distinctly declared is relatively short. I have made inquiries as to the progress of the cases whose symptoms and signs I have just analysed. The result of the inquiry is full of interest, particularly in its prognostic bearings. Complete records up to the present year in the case of the living, and up to the date of death in fatal cases, were obtained in respect of 48 patients whom I had seen during the previous 13 years. Exactly one-half of them survive and have reached the average age of 55 years. Some are disabled; others are said to be well and at work. The other 50 per cent. have died, at the average of 52 years: 25 per cent. of them suddenly; 21 per cent. from cardiac failure, with dropsy; 4 per cent. with apoplexy; 8 per cent. from aneurysm; 4 per cent. with Bright's disease; and a few from diseases unconnected with syphilis, or obscure, or of undetermined nature.

The average duration of the disease from the date of the first symptoms in the circulation in the 24 patients still living proves to be 4·6 years; in the 24 fatal cases it was 5·3 years. These figures afford striking evidence of the gravity of syphilis of the heart and aorta, and justify my contention that the question of causation should never be neglected in the diagnosis of cardio-vascular degeneration. But let me repeat that the figures are averages only, and represent neither the insecurity of life that characterises syphilis, nor the occasional quiescence of it for a considerable period. From the first recognisable symptom till death the duration in two instances was but a few months. On the other hand, one of the patients still living had his first cardiac symptom 23 years ago.

Once recognised, the disease may be watched pursuing a different course in different cases. Activity, as manifested more particularly by pain, may continue unchecked, the patient being unable to take exercise without suffering. But in the majority of instances treatment based on correct diagnosis comes to his relief for a time. Under complete rest and anti-syphilitic medication, pain is controlled, and presently it disappears, and quiet occupation may be safely resumed. Neglect of precautions is readily followed by an attack of angina, which drives the patient once more to bed. Meanwhile physical examination may reveal the progress of the disease, as it were, anatomically. A diastolic murmur makes its appearance, significant of descent of the syphilitic process on the area of the aortic valves. But, as we saw in connexion with the physical signs, the mitral cusps commonly remain intact. My observations to this effect confirm Sir Clifford Allbutt's statement that in syphilis of the heart and aorta the heart below the aortic valves, save for some endocardial opacities, is healthy. The area of manubrial dulness extends, consequent on aortic dilatation, and other signs and the symptoms of aneurysm of the arch may be developed. In one case, that of a woman, invasion of the mediastinal tissues was traced from its commencement to the sudden death of the patient. In other instances advance moves in the direction of the myocardium—through the coronaries, which are found post mortem to be affected in no less than 71 per cent. of visceral syphilis, according to Hirschfelder. Short of sudden death, the walls of the heart undergo slow degeneration, and the ordinary symptoms of cardiac failure make their appearance. Or the effects of syphilis on the brain, kidneys and other organs complicate the clinical picture, and possibly carry off the patient.

Syphilis obviously is to be classed among the causes that produce disease of the heart and arteries solely by damaging the substance of their walls. There is no question here of high blood pressure being concerned in the production of the primary lesions. But these lesions once produced yield to ordinary, much more to extraordinary, internal pressure; and some of their pathological characters, both destructive and constructive, are thus to be accounted for.

AN ABSTRACT OF

The Samuel Hyde Memorial Lectures

ON

OUTLINES OF MEDICAL HYDROLOGY.

Delivered before the Balneological and Climatological Section of the Royal Society of Medicine on May 15th, 17th, and 19th, 1911.

BY R. FORTESCUE FOX, M.D. LOND., F.R.MET.S.

LECTURE II.[1]

Delivered on May 17th.

MODERN HYDROTHERAPY.

THIS is the branch of medical hydrology which has to do with the use of water solely as a vehicle of energy. The foundations were laid in England by Floyer (1697), Wright (1779), and Currie (1797), whose teaching was zealously followed abroad. The methods of Currie were introduced by Franck into the hospitals of Vienna in 1803, and it is said that the typhus epidemics of 1811, 1812, and 1814 were largely treated by cool baths. The nineteenth century witnessed the popular movement led by Priessnitz (1830), which became systematised as "hydropathy," and may be regarded as a protest, not only against an artificial pharmacology, but against the general therapeutic scepticism to which this pharmacology had led in the middle of the last century. It is evident therefore that the ground was well prepared for the advances of any physical method that appeared to offer a substantial hope of combating disease. Unfortunately, this treatment, on the whole and in most cases, fell into the hands of irregular practitioners, with whom "hydropathy" became an exclusive system, and the profession at large was estranged from its employment. The new system shared the fate of every other system in medicine. It was too systematic to be finally true.

But in Germany, upon the heels of Priessnitz began another and a very different movement. The effects of water upon the human body were for the first time submitted to experimental research. A long series of investigations was commenced, having for their object to ascertain the effects of water at different temperatures, and of mechanical stimulation, upon the circulation, upon the nerve centres, and upon the general metabolism. The *reaction* of the living tissues, and especially the all-important *reaction to cold*, upon which the whole effect of cold baths depends, were now for the first time accurately observed. A beginning was also made in describing the variations of reaction in health and in disease. As a result of many experimental and clinical studies the indications for baths of different temperatures have been provisionally laid down, and rules of practice formulated. Among a great number of workers in Germany and Austria who have contributed to this research Professor Winternitz of Vienna holds the foremost place. At Berlin the "University Hydrotherapeutic Institution" was opened at the Charité in 1901, and placed under the care of Professor Brieger. In 1905 it was incorporated with the University Polyclinic, of which it became the hydrotherapeutic section for purposes both of treatment and teaching. The extent and importance of the practice may be inferred from the fact that last year between 5000 and 6000 persons were there treated. At Munich the Bavarian Government has added a complete and elaborate hydrotherapeutic equipment to the University clinic. Leipsic, Heidelberg, Tübingen, and Jena have also university clinics for hydrotherapy. That of Jena was founded in 1890 and has furnished opportunity for the valuable Text-book of Clinical Hydrotherapy by Mathes.

The establishments for water treatment that have been founded in France and the entire therapeutic procedure have been placed under skilled medical direction. This practice has therefore to a much greater extent than in England taken its place as a recognised branch of therapeutics, especially in chronic and nervous affections. The douche bath, which in its various forms has, as we have seen, been brought to a high pitch of perfection in France, was extensively

[1] Lecture I. was published in THE LANCET of July 1st, 1911, p. 6.

employed by Charcot. It is more than 50 years since the first institutions for treatment of this kind were set up in Paris under skilled medical direction, such as those of Beni-Barde and Keller. There is now a similar provision for medical practitioners in most of the great towns in France, and in many cases suitable baths are attached to hospitals, which are available for the use of all medical men.

In the United States modern hydrotherapy was introduced soon after Currie's work was published, but, as in England, with excesses that brought about a speedy reaction. In recent years the translation of the *magnum opus* of Winternitz (1884) and the valuable work of American writers have brought about a revival of the practice upon rational lines. Dr. Baruch now holds the chair of hydrotherapy in the University of Columbia—the first appointment of this kind in America. Well-appointed establishments have been founded in several cities in America, where baths and other water treatments are given under the observation and direction of trained physicians.

Statements are now made regarding hydrotherapy which are sufficiently striking in their character: that by it we can influence both acute and chronic disease by modifying physiological and pathological processes, not alone in one organ or tissue, but throughout the body, and can check the excessive reaction of acute disorders. In part this is a revival and amplification of older doctrine, of the teachings of the seventeenth and eighteenth centuries. What is new, and cannot fail to impress the candid mind, is the body of research that now lies behind them. It challenges examination and criticism at every point. Is it possible to disregard such a mass of evidence? The best answer to this question would be a complete experimental investigation upon English soil into the properties and uses of waters at different temperatures. We have as yet no Institute of Hydrology in this country, but I do not despair of such a research being some day accomplished.

FORMS OF HYDROTHERAPY IN CHRONIC DISEASE.

Certain forms of hydrotherapy in chronic disease have more particularly come under my own observation. Three distinct phases of treatment may be distinguished according to temperature in relation to the body. First, *plus* applications of heat; secondly, *plus* applications followed by *minus;* thirdly, *minus* applications.

1. *Brief hyperthermal baths.*—For many years I have used and valued these baths in a variety of chronic circulatory conditions. Chief among them is the state of habitual chilliness, and defective peripheral circulation and catarrh, met with in many persons in our country, often young persons of gouty inheritance. The deficiency of bodily heat appears to be conserved by a protective contraction of the peripheral vessels. The blood temperature is subnormal, that of the skin much more so. These are the subjects of internal congestion, intestinal irritability, and catarrh. The abnormal condition of the skin is matched by a corresponding disturbance of the mucous membranes. Such individuals are temporarily cured in a hot climate. They are in the same manner relieved by a course of hyperthermal baths. The temperature of the bath may in many cases be made to increase by daily increments of one degree from 108° or 110° to 115°, 118°, or even 120°. The duration of the bath is from one to one and a half, or at most two and a half minutes. The brief bath gives time for the primary stimulant operation of heat. The secondary and depressing effects that would follow a more prolonged bath are not developed. This practice was suggested to me by the natural hyperthermal baths of Japan. Local hyperthermal baths can be suitably employed in many cases of chronic traumatism, and in arthritis and neuritis where pain and atrophic and degenerative changes are to be attributed to a habitual deficiency of blood-supply.

The following methods illustrate the wide range and therapeutic value of the effects that are produced by minus applications.

2. *The cool or cold douche.*—This procedure is one necessarily of brief duration. It is comparable to the hyperthermal bath, inasmuch as it evokes the primary and stimulating results of thermal applications, but by brevity of application excludes those that are secondary and debilitating. I can add my testimony to that of others who claim for the cool douche a valuable place in the treatment of anæmia, in neurasthenia, and other functional nervous disorders, and to this I would add many cases of degenerative arthritis. It must be remarked that in douches having an appreciable pressure the effects of mechanical excitation are added to those of temperature.

3. *The subthermal douche bath, without pressure.*—I cite this mode of hydrotherapy as one that is but little appreciated in this country, although in my opinion of the greatest value. It is applicable to many of the more serious forms of cardiac disease, in which immersion baths are contra-indicated. The water flows over the patient, seated or reclining, without mechanical excitation, and with a temperature at or about that of the skin. The gentlest massage may be combined with this applicable. The whole effect is to soothe and stimulate the heart's action, and by opening up the peripheral circulation to relieve stasis and unequal distribution of the blood. The good effects of the bath depend on the nice adjustment of temperature and duration, with suitable precautions against fatigue.

POSITION OF HYDROTHERAPY IN ENGLAND.

It is remarkable that whilst modern hydrotherapy has taken a prominent place in the medical practice of nearly every civilised country, in England it is still comparatively unknown to us. It would almost seem that this country has been in two successive centuries so thoroughly inoculated with the empirical virus that it remains immune to the invasion of legitimate science. Here and there methods of hydrotherapy are studied and applied by practitioners, particularly at the mineral spas, but by the general body of medical men they are for the most part ignored, or employed for their patients in the least favourable manner, without the necessary exactitude and under the direction of persons who have received no medical instruction or technical training. Nor is it taught at any of our schools. British medicine cannot compare at present in these respects with the practice of Germany, Austria, Italy, America, and France.

For many years I have been impressed by the need for suitable Institutes of Hydrotherapy in this country. They might well be modelled on the pattern of the baths at Boston, open to the use of all medical practitioners, under skilled professional control, and served by attendants trained in the technique and in the use of instruments of precision. From such institutions the services of the attendants would be available outside for the treatment of acute disease. Within its walls many physicians who have to deal with chronic disorders would find new and unexpected possibilities. And the remedies would be applied, as they should be applied, under their own care and observation. Moreover, the great interest of conducting a course of physical treatment, with the necessary skilled assistance, would stimulate many medical men to independent research, and would in time confer educational value upon an institute of this kind. What I have said applies to most of our large towns, but especially to London.

In the western division of Glasgow there has lately been opened an establishment of medical baths, which are given by skilled attendants and under medical prescription. There is also in London the new Alexandra Institute of Baths which is conducted on similar lines, but I am not aware of any others in this country that are at all comparable to the hydrotherapeutic institutes existing in the other countries to which I have referred.

In many of our hospitals baths are employed, but not, so far as my information goes, to a considerable extent, either for acute or chronic maladies. We have witnessed the zeal with which in late years phototherapy, electrotherapy, radiotherapy, and treatment by massage and movements have been introduced into the hospitals and into general practice. I cast no doubt upon new treatments by entering this plea for a much older one. I am informed that at Guy's Hospital during the last year 43,000 treatments were given in the new department of electrotherapy and actinotherapy. How many of the patients so treated would have derived equal benefit from applications of hydrotherapy given with as much skill and precision! It is no doubt because during recent years we have called in aid so many physical agencies in medical treatment, both for the prevention and cure of disease, that a new hopefulness is abroad. We no longer despair of tuberculosis or even of cancer. We realise that there is a vast field open to us for increasing the resistance of the tissues to pathogenic invasion, and that this is, *par excellence*, the field of physical therapy.

In conclusion, we must acknowledge that there is a mass of evidence that diseased conditions can be controlled by applications of temperature in a watery medium. In our own lifetime there has been gathered together in reference to this subject as goodly a body of ascertained facts as can be found in any department of medicine.

But it may be said, Shall we touch what has been, or may be, in the hands of unworthy professors? Surely the extravagant or irrational use of a remedy should not prevent us from employing it wisely. Is it possible that we are willing to alienate a branch of therapeutics and yield up to the control of others what belongs to ourselves in trust?

Again, it may be said by some—perhaps by the practitioner at the mineral spa—How are we concerned with it? My answer to that is that the study of the laws of hydrotherapy, as we have received it in our generation, is an indispensable preliminary to his work. They form the very groundwork of his practice. Water cannot be separated from waters.

LECTURE III.

Delivered on May 19th.

THE MEDICINAL SPRING.

IN England there is no convenient name for the science dealing with the properties and uses of the medicinal spring—*crénotherapie* of the French, *heilquellenlehre* of the Germans. Health-spring lore must be regarded as a definite self-contained department of knowledge. The faith of mankind in waters rather increases with civilisation, and must be regarded as permanent. The primitive view attributed their virtues, as of all medicinal agents, to miraculous powers, and this belief was fitted to the old doctrine of possession in disease. Later, according to the humoral theory, the action of waters consisted in the elimination of peccant humours. Then with the growth of chemistry came the opinion that waters acted solely in virtue of their chemical ingredients as shown by analysis. This attractive explanation was in turn found not to cover all the facts, for "paradoxical" and "indifferent" waters produced effects out of proportion to the quantity or quality of their ingredients. In short, the known chemical constitution of many springs does not explain their action. We do not know the combination and dissociation of the elements, and the power one may possess in modifying the effects of another. It is believed in France that metals exist in some waters in the colloidal state, and probably act as ferments.

According to another view it is the water only that counts, and the particular qualities of the spring are negligible. This is not in accordance with experience. A bath of the natural water at Buxton produces a certain effect, a similar one at Droitwich a second, and one at Strathpeffer a third. These and such-like exhibit differentia which are superadded to something they have in common. The same remark applies to waters taken internally—at Bath, Harrogate, and Llandrindod. Much importance attaches to the *form* in which the ingredients are presented in solution. It seems that very dilute solutions are sometimes the most active. Jacoby points out that free motility of the particles of matter is essential to active metabolic processes. Water has the property of taking up molecules produced in dissociation, rendering them fluid and mobile and increasing their chemical activity. In many medicinal waters it is supposed that the saline constituents are in a state of complete dissociation (ionisation).

We here touch upon interesting and undetermined questions as to the range of active dosage, and as to the most favourable form of matter for absorption and assimilation. Recent knowledge does not appear to warrant dogmatic statements with reference to the inactivity of minute doses when presented in an assimilable form. The problem of treatment by many drugs is now no longer a question of "how much," but how to get the drug into the tissues, a problem which in my belief is often solved by medicinal waters. The osmotic pressure or tonicity of waters will probably have an important bearing upon their uses in future years. There is nothing to discourage the hope that many chronic tuberculous and pretuberculous conditions might be treated advantageously by hypodermic injections of diluted sea water and other natural salt water. It is premature as yet to attribute particular results to the radio-activity and electric properties of water. The effect of nitrogen and its congeners in waters like those of Buxton deserves further investigation. Carbonic acid gas in medicinal waters, whether taken internally or used as baths, powerfully modifies the action.

MODE OF ACTION OF MEDICINAL WATERS.

The treatment by means of medicinal springs concerns itself only with chronic disorders and morbid tendencies. It resembles the malady in being gradual, and it acts by absorption and by reiterated impression. The double appeal to the mucous membranes and to the skin was well understood by the early physicians. Waters and baths were called in aid for their purgative, diuretic, and diaphoretic effects. Although far from being the whole rationale of spa treatment, increased elimination from the bowel, the kidney, and the skin is an essential part of it. It is founded upon a humoral doctrine which still holds the field. Waters and baths also operate directly upon the circulation of the blood and upon the nerve centres, and so indirectly upon the general nutrition.

In chronic disorders the reaction of the tissues is perverted or inefficient. In place of the effectual reaction in acute disease, reaction is now imperfect, smouldering, and ineffectual. It is particularly for these more or less general chronic tissue disorders, which precede local and acute disease and furnish the soil for specific invasions, that spa treatment has its application. It is possible by the use of waters and baths to restore the healthy reaction of affected tissues. We know that in virtue of their selective or specific actions particular toxins cause a local neuritis, arsenic sets up or removes cutaneous changes, and iodine resolves deposits in connective tissues. By a similar selective action particular medicinal waters operate at the seat of disturbance. A certain striking increase of reaction signalises the conversion of the chronic process into one of a more acute character. As the lecturer has elsewhere shown,[1] this *intensive* action belongs to the natural process of cure, and its production is one of the chief principles in the treatment of chronic disease. *The intensive method* is at the foundation of hydrological medicine. Many waters and baths "bring out" the symptoms. Were this not so, the treatment would often be fruitless. The spa practitioner is concerned to watch these changes of phase, and in order to moderate the new reaction it may be well to combine with intensive and stimulant methods those of a more sedative character.

During the past century a mass of evidence has been accumulated as to the actual conditions in chronic disease, indicating the lines upon which treatment should be applied. It must in future be the aim of the physician to restore the normal resistance to invasion, to promote the elimination of toxins, and to allay nervous irritation and disturbances of circulation. On the other hand, we have a corresponding mass of evidence showing the effects of baths and waters upon nutrition, metabolism, and elimination, and upon nervous and circulatory disorders. From two sides, therefore, light has been focussed upon medical hydrology. Only in our time has it been established: first, that chronic disease depends upon intimate tissue disorders, with consecutive circulatory and nervous disturbance; and secondly, that waters and baths by their eliminative, sedative, stimulant, and intensive actions provide for this class of disorders an adequate treatment. It only remains to secure the recognition of hydrotherapy and the medicinal spring (medical hydrology) by the teaching bodies in the profession.

THE TEACHING OF MEDICAL HYDROLOGY.

Taking the countries as a whole, in France there is one chair of hydrology, and lectures are given by professors agrégés at the various universities from time to time. In Germany there is one chair of hydrotherapeutics, and regular lectures are given in both branches of hydrology at ten of the universities. In Austria and Hungary there is one chair of balneology, and lectures are given in both branches at Vienna, Prague, and Budapest. In Italy there is no chair, but there are "free teachers" at five universities. There are also free teachers in the Universities of Switzerland, Holland, Belgium, and Sweden; and in America there is one chair in hydrotherapy. Most of these educational facilities have been provided within the last 20 years. In general, the subject has not been made obligatory, and lecturers sometimes write "not an examination subject, therefore the lectures are badly attended." But at some universities questions on hydrology are included in the medical examinations. At the

[1] THE LANCET, April 23rd, 1910, p. 1115.

Columbia University hydrotherapy is a necessary part of the curriculum, and at certain universities in Germany.

If we are right in thinking that physical therapeutics, and especially medical hydrology and climatology, have taken, and are destined to hold, a large part in medical treatment, especially in chronic disease, surely it follows that these subjects must be taught as an essential part of a medical education. If it be objected that it is impossible to extend an already overloaded curriculum, it may be questioned in reply whether it is the instruction in therapeutics that ought to be omitted. Has not medical practice already run far in advance of systematic teaching? To point out the entire absence of this teaching from Britain is tantamount to urging the necessity for it. How would it affect the general practitioner? If this practice and teaching were cultivated in Britain it would open to him the resources of scientific hydrotherapy. How would it affect the practitioner at the British health resorts? We need scientists and observers at every health resort, whether a climatic or a hydromineral station. Undoubtedly many of the practitioners at our spas have, to their honour, qualified themselves by scientific studies for their special work. But is it not certain that in future years a medical man duly instructed in hydrology, and holding a British diploma in hydrology, will be a better spa physician than one who has enjoyed no facilities for instruction and qualification in the department of medicine to which his work belongs? It must needs be that the due qualification of the health resort practitioner is in the best interests of the profession at large.

Again, it may be said that there is less need for a chair of hydrology in our country, as compared with France or Germany, because our medicinal springs are comparatively few in number. But London is, or ought to be, in medicine also, the capital of the Empire. Twelve years ago I had occasion to make some inquiry as to the medicinal springs of India, in which I was much beholden to Sir George Birdwood and the late Sir Joseph Fayrer. The conclusion arrived at was that we have in India one of the most valuable and extensive and varied. if not the most valuable, group of medicinal springs in the world, many of them situated in fine climatic stations. I will only mention the Hazaribagh district in Bengal, where the country for more than 100 miles in all directions is teeming with thermal springs at an elevation of about 1500 feet, and the remarkable Tawala Mukhi (Flame's mouth) in the Kangra district of the Punjab. A recent inquiry at the India Office elicits the surprising fact that up to the present time there has been no scientific report made upon the mineral waters of India. The thermal springs of New Zealand form another group of exceptional value and interest, a fact which, I am happy to say, has been recognised by the Government of that colony.

RESECTION OF THE POSTERIOR NERVE ROOTS OF SPINAL CORD.[1]

BY PROFESSOR FÖRSTER OF BRESLAU.

FIRST of all I wish to thank you most sincerely for your kind invitation to this meeting of the Surgical Section of the Royal Society of Medicine. I am conscious of the great honour you have bestowed upon me by allowing me to attend your illustrious assembly. I would also express my deepest gratitude to Mr. Hey Groves for his kind words of welcome. At the same time I feel particularly glad to take part myself in this discussion on the resection of the posterior nerve roots of the spinal cord, since my own researches on this subject have received the greatest stimulus from English workers, especially from the discoveries of Sherrington and Dr. Henry Head. I need not mention before this audience how much we are indebted to Sherrington for all our knowledge of the physiology of the posterior spinal nerve roots, and that the work of Head on the disturbances of sensation in diseases of the viscera represents the most valuable document of our knowledge of the sensory nerve-supply to the internal organs.

Resection of the posterior spinal nerve roots for the relief of pain has already been carried out in the past in a considerable number of cases—e.g., by Abbe in 1888 in two cases of neuralgia of brachial plexus, by Sir Victor Horsley in two cases of severe neuralgia of the arm, by Chipault in five cases of neuralgia of the arm, by Giordano in a case of sciatica, and by Faure in a case of inoperable cancer of the uterus. In three cases of cancer of the spinal column Tietze and I performed resection of the posterior roots in order to relieve the fearful pain which radiated from these roots; but the results were only successful for a short time, since owing to the progress of the disease other roots were subsequently attacked. In 1900 Mingazini suggested resection of the posterior nerve roots in cases of locomotor ataxia with severe lightning pains, but the operation has not been actually performed until recently, when Hildebrand in 1910 cut two cervical nerve roots in a patient suffering from tabes; a relapse occurred. Enderlen performed resection of certain thoracic roots for severe girdle pain. Mr. Hey Groves has to-day reported to you a case in which also the pain remained. Last summer Gottstein and I cut the fourth and fifth lumbar and first sacral roots in a tabetic patient suffering from a perfectly localised neuralgia of the internal malleolus. For some weeks there was complete absence of pain, but afterwards it recurred as badly as before. I am inclined to believe that, if resection of the posterior nerve roots is to be performed at all in cases of tabes with lightning pains, it will be necessary to remove all the roots of one extremity at once, for we never know with absolute certainty which roots are particularly influenced by the morbid stimuli, and there is considerable overlapping of the regions supplied by the different roots. Thus, in our case of tabes the resection of three roots was not followed by any sensory disturbances.

When I suggested performing resection of certain posterior thoracic roots in cases of visceral crises I was influenced by a consideration of the severe pain and symptoms of sensory irritation, which form the basis of these crises, and of the often enormously increased hyperæsthesia of the skin of the epi-, meso-, and hypo-gastrium which accompanies the crisis. In the manner in which patients are wont to describe and localise the pain in gastric crises, and in the abdominal hyperæsthesia, such crises show a marked resemblance to the sensory symptoms observed with certain organic diseases of the stomach, notably gastric ulcer, as well as diseases of the liver, gall-bladder, and intestine. With these diseases, also, marked hyperæsthesia of certain parts of the chest and abdomen occurs very frequently, as has been shown by the classical investigations of Head. I was thus led to the view that the gastric and intestinal crises in tabes were caused by an irritation of the sensory sympathetic fibres of these organs which enter the spinal cord through certain posterior thoracic roots. Supposing this view to be correct, the crises would cease after the resection of these roots. The operation has now been performed altogether 25 times, as shown by the following tabular list:—

25 Cases of Gastric Crises (22 Survived; 3 deaths).

20 successful ... ... 2 not benefited.

		Interval between operation and publication.
No relapse. 13 cases.	1 Küttner	5 months.
	1 Küttner	1½ years.
	1 Haan	7 weeks.
	1 Goetzel	3 months.
	1 Becker	3 ,,
	1 Guleke	2 ,,
	2 Nonne	Interval not stated.
	1 Sänger	
	2 Sick	
	1 Franke	
	1 Franke	
Relapse. 7 cases.	1 Sauerbruch	—
	3 Tietze-Förster	
	3 Guleke	

Three cases succumbed to the immediate effects of the operation; two showed no improvement, the crises persisting.

DESCRIPTION OF ILLUSTRATIONS.

Figs. 1, 2, and 3 are from Case 2 before the operation. Fig. 1 is the patient supported in an upright position, showing the adductor spasms. Fig. 2 shows the slight amount to which the leg could be moved, and then only with associated movement of the neck and arms. Fig. 3 is the patient attempting to sit up. Fig. 4 is from the same case after operation, the patient walking with a long stride. Figs. 5 and 6 are from Case 3 before and after operation. Figs. 7 to 10 are from Case 4. Fig. 7, patient lying down with arms and legs flexed and distorted. Fig. 8, the patient supported in the author's arms. Fig. 9, after operation, the patient standing with assistance. Fig. 10, after operation, patient seated and raising one arm with outstretched fingers.

In the remaining 20 cases the operation was successful. Immediately after the resection of the roots the crises disappeared, the body weight increased greatly, and the general condition showed a marked improvement; some of the patients, who until then absolutely had been confined to their bed for some long time, have since regained their power to work. In the majority of these cases (13) no relapse has been reported. The period which has elapsed since the operation is shown in the table. In several of these cases there has been no recurrence of the crises for many months and even for over a year, although before the operation a continuous critical state had persisted. In the remainder of the cases (7) the crises ceased for a while, but subsequently recurred. Yet, even in these, the critical state has not returned. The crises only occur occasionally, at long intervals; they are of short duration and moderate intensity. Among this latter group of cases are three patients who have regained the power of earning their living, one of them being an architect and one a mason.

In a number of cases the result of the operation is not perfect, because the system of roots carrying sympathetic nerve fibres of gastro-intestinal origin is very extensive. By the method which has hitherto been practised of only cutting the seventh to ninth or the seventh to tenth thoracic roots the source of the crises is not always entirely eliminated. Probably the fifth and sixth, as well as the eleventh and twelfth, thoracic roots are also concerned. It is therefore desirable to remove as many of the nerve roots as possible, although naturally this increases the gravity of the operation. What is even more important is in every case to determine exactly the situation of the pain, the extent of the hyperæsthesia of the skin, and the site of its maximum intensity, since these data may possibly afford a guide which roots are chiefly irritated and concerned in causing the crises. In this connexion a publication by Guleke is of interest; in one patient the crises disappeared for a time after the resection of the seventh to the ninth thoracic roots. They recurred, but again disappeared after the resection of the tenth and eleventh thoracic roots. For such extensive resections Guleke's method would appear to be particularly well suited. While ordinarily the dura is opened and the posterior thoracic roots are resected close to the spinal cord, Guleke does not open the dura, but picks up the roots in their course outside the dura. Here also the anterior and posterior roots are enclosed in separate sheaths separable from one another with comparative ease. The posterior roots are then cut. We must, however, bear in mind that gastric crises may possibly arise from irritation of the pneumogastric nerve, and perhaps even of the vomiting centre in the medulla. All cases of gastric crises without any pain should be regarded as suspicious and as unsuitable for resection of the posterior nerve roots.

I will now discuss the value of resection of the posterior spinal nerve roots in spastic paralysis due to disease of the cortico-spinal path, especially the pyramidal tract. These paths carry two kinds of fibres—firstly, those bearing the motor impulse, injury to which causes paresis or paralysis; and, secondly, the inhibitory fibres which check the sensory stimuli entering perpetually into the grey matter of the spinal cord by the sensory nerve roots. As a result of damage to the latter class of fibres the sensory afflux acts unrestrained upon the muscles, thus causing the spastic symptoms. If in such cases the posterior roots—i.e., the path of afferent sensory impulses—are cut, the excess of sensory impulses is again reduced and the spastic symptoms are diminished or may even disappear completely. Frequently the fibres carrying the motor impulses are still fairly intact; in such cases resection of the posterior roots is followed by a complete disappearance of the spasms, and all those voluntary movements which were so seriously interfered with by the spastic resistance of the muscles are now executed without any difficulty. We may therefore conclude that the operation can only be successful where voluntary excitability of the muscles is still present to a certain extent. Further, this treatment can only cure those spastic conditions of the muscular system which are actually due to the influx of excessive sensory stimuli to the grey matter of the cord—i.e., only in true reflex spastic contraction of the muscles; on the other hand, resection of the posterior nerve roots cannot be successful in the muscular contractions of athetosis, chorea, mobile spasm; for this latter class of diseases, which have so often been confused with the former, are due to the direct pathological stimulation of motor centres and paths belonging to the cerebrum and mid-brain; they are therefore comparable to the epileptic convulsions which arise from a corresponding irritation of the motor centres of the brain. Resection of the posterior roots cannot eliminate the pathological stimulus of the centres. In all such cases it has therefore proved unsuccessful. The operation has hitherto been performed in 58 published cases, to which must be added 4 unpublished cases, 3 of which were operated upon by Küttner and 1 by Tietze, giving a total of 62 cases.

61 Cases of Spastic Paralysis (56 survived; 5 deaths).

37 cases of congenital spastic paraplegia (Little's disease): successful; 1 not benefited.

3 cases of acquired cerebral spastic paraplegia: all successful.

4 cases of spinal spastic paralysis of traumatic origin: 2 successful; 2 not benefited (1 case wrong roots divided, 11 Th., 12 Th., 1 L; 1 case complete interruption of the cortico-spinal tracts).

1 case of spastic paraplegia from compression of the spinal cord (Pott's disease): successful.

2 cases of syphilitic spastic paraplegia (Erb): successful.

1 case of primary spastic paraplegia (? Erb-Charcot): successful.

2 cases of disseminated sclerosis: 1 case not benefited; 1 case successful, disease rapidly progressing, death.

7 cases of spastic paralysis of the arm: 5 cases benefited; 2 cases not successful—complete interruption of the cortico-spinal tract.

Of these, 5 died as the result of the operation and 57 survived. 38 of the survivors were cases of congenital spastic paraplegia (Little's disease); almost all these patients have been benefited by the operation, some of them showing a very marked improvement. I should like to demonstrate to you in pictures the extent of this improvement in some cases. The patients in question were operated upon by Küttner and myself, a part only of these cases having been published.

CASE 1.—Boy, aged 7 years. Severest rigidity of the limbs; unable to make the slightest voluntary movement, to sit, stand, or walk; the patient lies in bed like a log. Preliminary orthopædic treatment consisting in tenotomy of the Achilles and adductor tendons had been absolutely of no avail. The rigidity had the same extent as before; the paralysis was as complete as before; the legs were now held in extreme abduction with the same rigidity as they had previously been held in adduction. The result of the operation of root division was immediate cessation of the spasms and the return of voluntary motility. The boy now moves his legs freely; he even lifts one leg alone without any assistance; he can stand erect with straight knees, unaided, and walks quickly and safely on two crutches without any help. The improvement was maintained under the use of suitable exercises, and is still going on.

CASE 2.—Boy, aged 11 years. Severest rigidity; was able to carry out slight voluntary movements of the legs, but could only bend both legs a little at the same time, considerable subsidiary movements being carried out with the arms and head. The patient was quite unable to stand or to walk, and could not sit up even when assisted, the resistance of the extensors of the pelvis being insurmountable. After the operation the rigidity quite disappeared; voluntary movements of the legs are carried out freely, the patient being able to bend each leg by itself, to lift it up high without also bending the knee- and ankle-joint, and to sit, stand, and walk alone with long strides. (Figs. 1, 2, 3, and 4.)

CASE 3.—Boy, aged 10 years, with severe rigidity of the limbs and contraction of the flexors. Motility as in the previous case; the patient was unable to sit, stand, or walk. After the operation the spasticity quite disappeared and perfectly free motility was obtained, the patient being able to bend each leg independently or to lift it high up, and to abduct the legs widely; the patient stands and walks alone with long steps; he bends the leg well in walking and steps well forwards, mounts stairs without fatigue, and is out alone in the open for many hours. (Figs. 5 and 6.)

CASE 4.—Unpublished case. Severest spastic paralysis of all four limbs, the figures showing how arms and legs were inextricably interlocked, as it were, in a tangle. The patient was totally unable to carry out any voluntary movement, lay in bed huddled up, and, in addition, suffered from athetosis. Root resection was carried out here, both in the lumbo-sacral and the cervical part of the cord. The spasms were greatly improved. The patient can now lift up each leg separately. In standing and walking he has still to be supported on both sides, since the operation was carried out comparatively recently. The patient voluntarily lifts each arm up high, and can use his hands in eating and drinking. In another similar case of spastic diplegia Küttner has performed resection of the cervical, as well as the lumbar roots too, with success. (Figs. 7, 8, 9, and 10.)

On returning to a consideration of the table we next find the following cases: three patients with acquired cerebral spastic paralysis, all of which were treated successfully, one of them being a case of hydrocephalus with severe spastic paraplegia. There is also a considerable number of cases of spinal disease with spastic symptoms. Of 4 cases of spinal spastic paralysis of traumatic origin 2 were successful; of the remaining 2, which were failures, in one wrong roots were cut, whilst in the other the cortico-spinal fibres appear to have been completely interrupted; in this case the spasms disappeared, but voluntary motility did not return. In addition there was 1 case of Pott's disease which was successful; also 2 cases of syphilitic spastic paraplegia (Erb), successful; 1 case of primary spastic paraplegia (Erb-Charcot), successful; 2 cases of disseminated sclerosis, one of which was no

benefited, whilst the other was at first successful, but subsequently the disease progressed rapidly and the patient died. Of 7 cases of spastic paralysis of the arm 5 were successful—one of these being Case 4 already demonstrated. The remaining two were not benefited owing to complete interruption of the cortico-spinal paths; in these patients the spasms disappeared, but voluntary motility did not return. These are the cases, to my knowledge, mostly published hitherto. To these must be added the three cases which Mr. Hey Groves has reported to-day.

There remain still a few points to which I would call your attention. As regards the indications of the operation I must in the first place repeat, that only lesions with real reflex spasticity, as the result of the loss of the cortico-inhibitory fibres are suitable, but not the diseases of the type of chorea, athetosis, mobile spasms, and spasmodic torticollis; possibly, however, Parkinson's disease may be suitable. Secondly, there must be a reasonable prospect of innervating fibres of the pyramidal tract still existing, all cases with slight spasms and considerable paralysis being unsuitable. In cases of severe spasms and total voluntary paralysis there may remain a considerable amount of voluntary excitability, only obscured by the spasms and only apparent after their elimination. In such cases the experiment is worth trying. The question whether any voluntary motility remains may be decided by preliminary injection of stovaine, which temporarily removes the spasms. The arm, as a general rule, is less suitable than the leg. Thirdly, the disease must have become practically stationary, whilst progressive diseases like disseminated sclerosis are hardly suitable, very slowly progressing ones, like spastic spinal paralysis, being perhaps more promising.

The second point to which reference should be made is the after-treatment of the patient. Good results can only be obtained with very careful exercise treatment. It is only by such exercises that voluntary motility is brought up to its highest level, and that, above all, standing and walking are gradually rendered possible. Such exercises should be continued for years, during which continuous progress may be observed. The assistance of orthopædic measures cannot be dispensed with; above all, it is necessary to place the limbs in removeable plaster splints in such a position as to correct the previous deformity, the legs in abduction, extension and outward rotation, the knees in extension, the feet in dorsal flexion; the arms in abduction, the forearms in extension, the hands in supination and extension, the fingers in extension, the thumbs in opposition. These positions are required during the whole time immediately following the operation, the limbs being only removed from their plaster cases for the purpose of the exercises, which should be carried out several times a day; later they should still be kept in the splints at night. If beside the real spastic contractions there are also organic contractions due to shrivelling of the muscles and tendons, tenotomy or tenoplasty may also have to be performed.

As to the technique of the operation I am fully convinced that Mr. Hey Groves's proposition for the use of adrenalin is of the greatest importance, as the bleedings often assume a threatening character. It seems to me also that his method of cutting the roots nearer to the spinal cord simplifies the operation, although it renders it more difficult to distinguish the different roots.

In conclusion, let me thank you for the kind attention with which you have honoured me and the leniency you show me for my inefficient use of your tongue.

Note.—A full list of references is appended to the articles by Professor Förster and Mr. Hey Groves in the Proceedings of the Royal Society of Medicine.

Dr. W. J. Seward, medical superintendent of Colney Hatch Asylum, has resigned his position as from the end of September next. Dr. Seward has been connected with the asylum for more than 33 years, first as an assistant medical officer, then from January, 1882, as medical superintendent of the male department, and since May, 1890, as medical superintendent of the whole asylum. The sub-committee of the asylum has expressed its appreciation of Dr. Seward's services and of his care and anxiety for the patients' welfare.

ON THE DIVISION OF THE POSTERIOR SPINAL NERVE ROOTS:

(I.) FOR PAIN; (II.) FOR VISCERAL CRISES; (III.) FOR SPASM.[1]

BY ERNEST W. HEY GROVES, M.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE COSSHAM HOSPITAL, BRISTOL; ASSISTANT SURGEON TO THE BRISTOL GENERAL HOSPITAL; SENIOR DEMONSTRATOR OF ANATOMY AT THE UNIVERSITY OF BRISTOL.

SINCE Abbé in 1888 first divided the posterior spinal roots for the relief of intractable pain the number of cases recorded of this operation has been remarkably few, but in quite recent years Förster has given a new stimulus to the subject by his suggestion that the scope of the operation may be extended to the treatment of such diverse conditions as visceral crises and spastic contractions. With the exception of isolated cases reported by Bennett, Horsley, Head, and Morton Prince there has been practically nothing written on this subject in England. And yet from both the physiological and the clinical standpoints it is one of great interest and importance. For on the one hand it demonstrates and to some extent elucidates the complexities of the problems of pain, whilst, on the other hand, it offers a cure for certain disorders which are otherwise almost intractable. Strangely enough, the division of the posterior spinal roots has given the least satisfactory results in those very cases where we should have expected it to have been the most efficient—i.e., in the relief of pain—whereas in symptoms with which it is much more remotely connected it has never failed to yield some measure of success.

I have to report six cases of posterior root resection, and I will preface my remarks on each subdivision of the subject by a short description of the personally observed cases which illustrate it.

SECTION I.—*For Pain.*

CASE 1.—Patient, aged 50 years. As he has always been of very methodical habits, and has kept a diary, the history of the onset of his symptoms is exceptionally precise and reliable.

History.—January, 1896, first noticed the loss of sensation in the left foot. February, 1896, first had pain in the left foot. September, 1897, the left foot swelled suddenly. November, 1897, first noticed lameness. Occasional pain noted in the right leg and foot. March, 1898, swelling

FIG. 1.

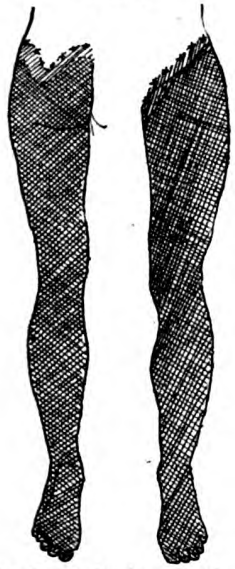

Diagram depicting Case 1, showing areas of anæsthesia. The small crosses show the margin of loss of pain sense, and the broken lines the margin of loss of tactile sense.

of the left knee. From May, 1898, to August of the same year was an in-patient at the Queen's-square Hospital for Paralysis, London, under the care of Dr. J. A. Ormerod. Then for the first time he had difficulty in micturition. For the next ten years the pain continued without much alleviation, occurring in severe paroxysms once or twice a week. It has always been most severe in the left leg from above the knee to

[1] A paper read before the Surgical Section of the Royal Society of Medicine, on June 13th, 1911.

the extremity of the foot, but the right leg has also been the seat of a good deal of pain. Since 1898 he has only been able to walk with the help of crutches because of the pronounced ataxia and the deformity of the left foot and knee.

Condition prior to operation (August, 1909).—He is a heavily built man, well nourished and perfectly healthy except in respect to the nervous system. Left leg: The knee is much swollen, measuring 22½ in. in circumference (as compared with the right, which is 15 in.). There is much bony thickening and free fluid with several large loose bits of bone. An extreme valgoid position is present at the knee amounting to about 30°, whilst there is nearly 15° of lateral mobility. The left foot is also in the condition of a typical Charcot's joint, being flattened, everted, and deformed. The pain, which is present in both legs, is much worse in the left, feels as if it were in the bones, is liable to sudden and severe exacerbations about every third day which last about seven to eight hours, generally at night, and is more relieved by antipyrin (30 gr.) than by any of the other innumerable things which he has tried. The sensibility to tactile, painful, and thermal stimuli is greatly impaired in both legs. The impairment of sensation in the left leg extends almost to the groin, in the right to the knee. The loss of sensation amounts to a dulling of perception with great delay, but not to absolute anæsthesia.

Laminectomy, August 16th, 1909.—The ninth dorsal spine was first removed in order to allow the turning up of a large osteoplastic flap, containing the tenth dorsal to the first lumbar laminæ, inclusive. After opening the dura it was found necessary to take away the second lumbar lamina as well in order to gain sufficient room. About a centimetre was resected from each of the following posterior roots on the left side—viz., the third, fourth, and fifth lumbar, and the first, second, and third sacral. For three days after the operation the patient had very severe pain, chiefly in the left foot, which required ¼–½ gr. morphia to be repeated twice a day. The bladder had to be emptied by catheter from this time onwards until the patient was able to get up.

Excision of the left knee-joint, August 30th, 1909.—The disorganised joint was excised, many large loose pieces of bone were removed, and the femur was united to the tibia by means of a mortice joint. The operation, which lasted one and a half hours, was well borne, *without any anæsthetic*, either local or general. After it was over the patient was a little pale and complained of feeling tired, but otherwise he had no sensation of discomfort from the operation. The wound healed by first intention with a good firm fibrous union between the bones. Osseous union was prevented by the strong contractions which were constantly taking place in the leg muscles.

Recovery from the operations was uneventful except for an unfortunate attack of suppurative parotitis on the left side which required an incision. The patient returned home on Oct. 21st, 1909. He had a small pressure sore on the left heel which was somewhat slow in healing. On two occasions the actual cautery was applied to this without causing him any sensation.

Present condition (February, 1911).—I have asked the patient to give his own opinion as to his present condition and the benefits he has derived from the operations. He writes: "The pain in the left leg has certainly been much less severe than previously. There has, however, been pain, though more of the gnawing than of the shooting description. I suffer enough, though, still to make life rather a doubtful blessing, and without heroin and antipyrin I hardly think I could go on with it. I do not think I would undergo the operation again ....., but if I had to do so would have it done *on both legs*. It has not affected my locomotion at all. If the pain I experience in my right leg were modified as it has been in the left, it would not then be unbearable. I only wish that the nerve operation could have been as successful as that of straightening the leg was." From an objective point of view, the left leg has lost sensation completely right up to the fold of the groin and round the iliac crest. (Fig. 1.) Tactile, painful, and thermal sensations are all quite absent over the whole of this area, but that of tactile sensation is not quite so extensive as that of the other two forms by an area of about two inches. The limb is well nourished and shows no muscular wasting, but he has on several occasions had some superficial ulceration between the toes, which has healed readily under ordinary treatment.

CASE 2.—The patient was a married woman, aged 30 years, with four children.

History.—In 1907 the patient had a severe attack of puerperal pyæmia which necessitated several operations for the opening of abscesses, the largest of which was over the left iliac crest, and was associated with partial necrosis of that bone. In the beginning of 1909 she had phlebitis in the left leg with a large indolent ulcer over the shin. This was the beginning of the pain, which has continued ever since. By the autumn of the same year the pain had become so unbearable that she begged to have the limb amputated.

First operation, Oct. 8th, 1909.—Laminectomy; division of posterior nerve roots. The eleventh and twelfth dorsal and first lumbar laminæ were removed, and the roots of the fourth and fifth lumbar and first, second, and third sacral nerves on the left side were divided. The patient had a good deal of pain in the back and left leg for about a fortnight after this operation, but was then much easier for a month. However, as very little loss of sensation could be detected in the left leg, it was feared that the division of the nerve roots must have been incomplete. This was confirmed by a speedy return of the pain in all its former intensity.

Second operation, Dec. 8th, 1909.—The lumbar enlargement of the cord was exposed by opening the former scar, cutting through very dense cicatricial tissue. This gave a much more bloodless field of exposure, and it was found that in every case some of the nerve filaments had been left to each divided root. These were now completely resected. After this the leg was absolutely anæsthetic to within one hand's breadth of the groin. No painful, tactile, or thermal impression could be felt in any part of this area, nor had she any idea of the position of the limb. On first attempting to walk, the leg was thrown about in the most wildly ataxic manner, but this slowly improved in time.

After-history.—For some few weeks the patient had relief from pain, but it then began to be as bad as ever. The pain nearly always began at night, and continued for many hours, making the patient roll about in agony and threaten to take her life. She said she felt as though the pain was driving her out of her mind, and this fear proved to be well founded, and she had to be removed to the Fishponds Asylum, where she remained from April 22nd to Oct. 3rd, 1910. For about one month of this time she was wildly maniacal, and she had to be kept in the padded cell. Her mental condition slowly improved, but the pain in her leg never wholly left her. On returning home she became much worse, and I admitted her again to the hospital for observation in January, 1911, but again she had to be taken to the asylum, where she remained until April. During both attacks of insanity the pain in the leg was better; then, after she had been discharged from the asylum, where she had been getting good food and fresh air, and had returned to a poor home, where she had every encouragement to ill-health, the pain would begin again.

Judging from *a priori* arguments we should certainly have supposed that in the section of the posterior spinal roots we have a certain means of curing peripheral pain. And yet we have the very remarkable phenomenon of complete and lasting analgesia associated with a continuance of a subjective feeling of pain, and it is easy to satisfy one's self that this result is the general rule and not the exception in similar instances recorded in the literature.

Among the 16 cases collected by Jacobi[1] in 1907 there are only six in which the pain is said to have been completely cured. In six others there is said to have been great relief, and of the remainder there is a significant silence about the after-results.

Knapp[2] has recorded two cases. The first was that of a man, aged 40 years, an alcoholic, whose leg was amputated in 1890 for trauma. Then during the next five years he had several excisions of the stump and of the bulbous nerve ends for pain, and finally, in 1896, the posterior roots of the sacral plexus were divided, but he died from shock. The second was that of a man, aged 25 years, in which amputation of the right arm below the elbow on account of a severe crush was performed in 1898. Great pain in the stump required four operations for the removal of bulbous nerve ends. The nerves were injected with osmic acid; the limb was amputated higher up with no avail. In 1899 he was nervous, hysterical, and generally wretched. In 1902 the sixth, seventh, and eighth cervical and first dorsal right posterior roots were resected. He was free from pain for some months and then became as bad as ever. Two years later he developed spastic paraplegia, and at that time and up to 1907 the original pain was as severe as ever, although the cord was re-exposed and the division of the nerve roots assured.

Chavaunaz[3] relates the case of a man, aged 68 years, who had severe intercostal neuralgia on the left side from the axilla to the mamma, which persisted in spite of excision of the corresponding intercostal nerves. The posterior roots of the first to the fourth dorsal nerves on the left side were resected, but the result was only "some amelioration, but not cure."

Hildebrand[4] recounts three cases. 1. A woman, aged 48 years. Luetic neuritis of arm, which was relieved by no medicines. The roots of the seventh and eight cervical nerves were cut on Feb. 23rd, 1910. Relief for a time, but the pain soon returned. A second operation on April 16th. Divided the sixth cervical and first dorsal roots, but sudden death occurred at the end of the operation from heart failure. 2. A man, aged 62 years. October, 1909, pain in right hip, thigh, and leg, with some muscular wasting. Arterio-sclerosis, œdema, and cyanosis of feet. Operation June 1st, 1910. Laminectomy of first to fifth lumbar vertebræ; resection of right posterior roots. Pain temporarily relieved, but by July 15th it had recurred as badly as ever in the right leg. 3. A woman who had been operated on seven years before for breast cancer. Metastatic growth in left brachial plexus, severe pain in arm. Operation July 16th, 1910; laminectomy with resection of posterior roots, fifth to eighth cervical and first and second dorsal. Good recovery. The patient declared she still had pain. This was considered to be due to the fact that she still craved for morphia.

These are all the cases of this kind that I have been able to collect from the literature, and they are enough to show pretty clearly what the general results have been. Some analysis of the details of the 24 cases included in Jacobi's list and those I have added may serve to emphasise the points of importance.

Sex.—17 males, 6 females; in one case the sex is not mentioned.

Age.—In 19 cases only is the age given, and the average is 41 years. The oldest was 68 and the youngest 15.

[1] Jacobi: New York Medical Journal, 1907, p. 192.
[2] Knapp: Boston Medical and Surgical Journal, January, 1908, p. 149.
[3] Chavaunaz: Gazette Hebdomadaire des Sciences Médicales, 1908, xxvii., p. 369.
[4] Hildebrand: Langenbeck's Archiv für Chirurgie, 1911, 94, ii., p. 203.

Exciting causes.—Mentioned in 10 cases: tabes, 1; cancer of brachial plexus, 2; pyæmia, 1; trauma, 4; syphilitic neuritis, 1; and athetoid paralysis, 1.

Region affected.—Arm, 15; leg, 6; intercostal areas, 3.

Immediate result.—Death in 4; recovery in 20.

Late results.—Complete cure of pain, 6; moderate or partial relief, 6; failure to relieve the pain, 3; not mentioned, 3; died within a few weeks (the two cancer cases), 2.

Nervous and mental sequelæ.—Moderate degree of Brown-Séquard paralysis, 1; spastic paraplegia (occurring some years after operation on the brachial roots), 1; morphia habit, 3 (acquired before the operation); insanity or other severe neurosis, 3.

The point of the greatest interest in these cases is the failure of the resection of the posterior nerve roots to cure the pain in the corresponding areas in about 75 per cent. of their number. A certain number of these cases may be accounted for by supposing either that not enough of the roots have been divided or that the division had been incomplete. But probably the majority are not susceptible of this explanation, and those I have related are among such, for in both these there was the most absolute loss of every kind of sensation, so that one patient could have his knee-joint resected without an anæsthetic, and yet pain is still referred to the same area. It is easy to understand that the relief from pain would not be immediate or that it might for a time be increased, as it usually is, but when the nerve tracts in the spinal cord have had time to degenerate it is hard to understand where the pain comes from. In the case of facial neuralgia the removal of the sensory ganglion or the division of the root of the fifth cranial nerve proximal to that ganglion causes immediate and lasting freedom from pain. Why is the result different when the neuralgia is in the area supplied by the spinal nerves? In some cases—e.g., the second which I have related—the pain is evidently of a psychical origin, and in her case it alternates with absolute insanity.

From a practical point of view it is clear that we must give a very guarded prognosis as to the results likely to be obtained by the resection of the posterior nerve roots for the cure of pain. But it is certainly a more rational and more hopeful proceeding than that of amputating a limb, for the former may cure, it often relieves, and it does not mutilate, whilst the latter never cures although it involves the sacrifice of a member.

SECTION II.—*For Visceral Crises.*

CASE 3.—A labourer, aged 34 years. Symptoms: pain, emaciation, and vomiting.

History.—The patient had always been healthy until two years ago, when he first began to suffer from vomiting and loss of flesh. For the last few months he has had daily lavage of the stomach, which has given him some relief. I saw him with Dr. C. W. M. Grier at Mevagissey, and we diagnosed his condition as being due to some form of pyloric stenosis. I admitted him to the Bristol General Hospital on August 1st, 1910.

FIG. 2.

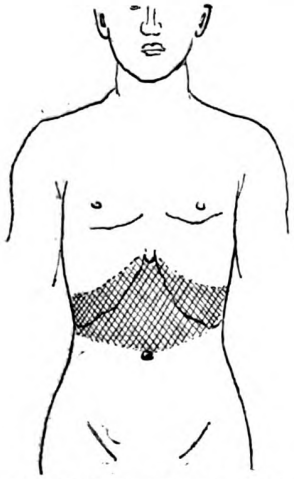

Diagram from Case 3, showing area of anæsthesia resulting from division of the seventh to tenth dorsal posterior roots.

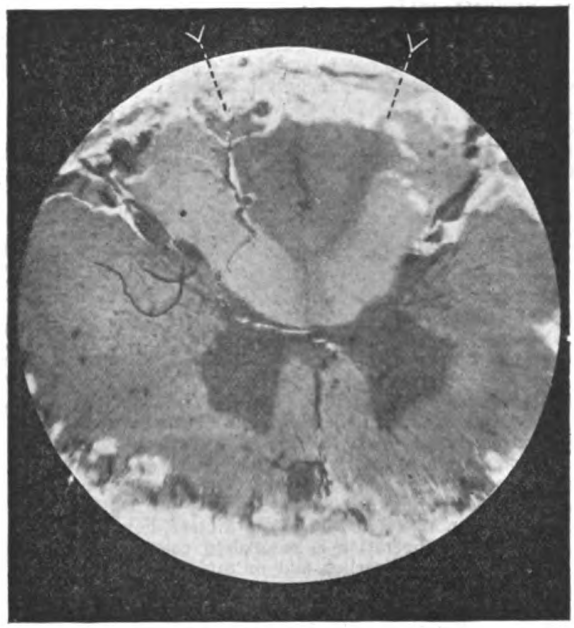
Condition.—The most notable thing about the patient was his great emaciation, he seemed to be a walking skeleton, weighing only 85 lb. He vomited several times a day, and had a great deal of epigastric pain. The stomach was dilated and displaced downwards to one finger breadth from the navel, and splashing could always be elicited over the organ.

First operation.—August 2nd, 1910. Gastro-enterostomy. The stomach was dilated and prolapsed, so that the pylorus appeared to be kinked. There was no evidence of ulcer or new growth. The usual posterior gastro-enterostomy was performed. He derived no benefit from this proceeding, but was as sick as before. About a fortnight after he complained of severe shooting pains in his legs, which suggested the idea that he might have tabes. Further examination by Dr. Carey Coombs confirmed this. There was an absence of knee-jerks, Argyll Robertson pupils, and Romberg's sign. The pain which I had mistaken for indigestion was in reality a girdle pain due to tabes.

Second operation.—August 26th. Laminectomy, fifth to eighth dorsal vertebræ; resection of the posterior dorsal roots, seventh to tenth inclusive. (Fig. 2.)

After-history.—For a few days the patient had increased pain, but this quickly subsided, and he was free from vomiting except for one or two occasions after the operation. He took his food well, but though on full diet he never gained flesh. This was largely due to the fact that he had several large loose actions of the bowels daily, which no kind of medication had any effect in arresting. He died quite suddenly on Sept. 21st, although at this time he was well enough to get up each day and go out of doors.

FIG. 3.



Section of cord in cervica region from Case 3. v v show the degeneration in the posterior columns.

Necropsy.—This was performed by Professor E. Emrys-Roberts. Nothing abnormal was found apart from the condition of the nervous system and the extreme wasting. The gastro-enterostomy junction was firmly united. The laminectomy wound was soundly healed.

Structural changes in the cord.—I am greatly indebted to Dr. A. Rendle Short, the senior demonstrator in physiology at the Bristol University, for a most careful examination of the cord. The dorsal and cervical regions show the degeneration of the posterior columns which results from the resection of the posterior nerve roots in the dorsal region. Many of the cells of the anterior horns of the grey matter in the dorsal region show marked chromatolysis. (Fig. 3.)

The idea that the gastric crises of tabes might be cured by division of the posterior nerve roots of the spinal segments governing the stomach is due to Professor Förster[5] of Breslau, who with Professor Küttner carried out the first operation of this kind in 1908, with very marked success. The patient was a man, aged 47 years, who had suffered from severe gastric crises since 1902, with great pain and almost incessant vomiting. He was worn to a shadow and was addicted to morphia. All kind of medicinal and electrical treatment had been unavailing. On Dec. 31st, 1908, the laminæ of the fifth to tenth dorsal vertebræ were removed, but the dura not opened. The pain and vomiting became much worse. On Jan. 1st, 1909, the sixth to tenth dorsal posterior roots were resected on both sides after opening the dura. After this the pain and vomiting absolutely ceased, and the patient gained weight rapidly. He

[5] Förster and Küttner: Beiträge zur Klinischen Chirurgie, 1909, 63 ii., p. 245.

died from phthisis nine months later, but had no return of the gastric crises.

Förster and Küttner's second case was that of a man who had become greatly weakened by the morphia habit. He died a few hours after the operation. Their third case was that of a man who had had two previous operations on the stomach, including a gastro-enterostomy. The sixth to eleventh dorsal posterior roots were divided on both sides and the patient has completely recovered his health, and this continues until the present, nearly two years after the operation.

Bruns and Sauerbruch's case[6] was that of a man who for several years had had gastric and intestinal crises of increasing severity, so that before the operation he often had fæcal vomiting. The seventh to ninth dorsal roots were divided with an excellent result. However, he suffered a relapse six months later, brought on by alcoholic excess. He subsequently recovered, so that he is now able to resume work (February, 1911).

Moskowicz's[7] first case was that of a man, aged 46 years, who for three years had had gastric crises. The resection of the posterior roots was followed by a cure which lasted for six weeks from the date of the report. His second case was that of a patient who died two weeks after the operation from sepsis of the wound.

Thomas and Hall's[8] case was that of a man, aged 32 years, with a history of gastric crises of eight years' duration. The patient's weight had dropped to 100 lb. He had the symptoms typical of tabes. In 1905 he had a laparotomy with the freeing of some gastric adhesions, but derived no benefit, On March 3rd, 1910, the seventh, eighth, and tenth dorsal roots were cut on both sides. He was relieved of the crises until the date of the report, July, 1910, but he had not cured himself of the morphia habit.

Hahn has had one very successful case and Gulicki several, but I have not been able to obtain the reports of these.

In all these cases the condition has been allowed to go on for several years (from two to eight) and the patients have been extremely ill from the combined effects of pain, emaciation, and morphia. Such patients are in the worst possible condition to recover from a severe operation, and the actual results obtained as to mortality are better than might have been expected. It is quite clear, however, that if the value of the operation is recognised cases will be sent to the surgeon much earlier, and in this event there is no reason for regarding the operation as a particularly dangerous one.

Before leaving this part of the subject it is of interest to refer to two operative procedures of a nature closely allied to that of Förster. The one is described by Cotte.[9] He had a patient who for from five to six years had had very severe gastric crises with other signs of tabes. On Jan. 28th, 1906, the abdomen was opened and the stomach was found to be normal. The solar plexus was freed from the cœliac axis and stretched. All pain and vomiting were completely relieved by this operation, and this relief was maintained at the time of the report five months later. It is difficult to believe, however, that a procedure of this kind can possibly be more than of temporary alleviation, but it is worth bearing in mind for those cases where the abdomen has been opened on account of intractable vomiting and where no gross disease of the stomach is found.

The other suggestion is contained in some remarks by Frank[7] during the German Surgical Congress when Förster's operation was under discussion. He states that it is possible to sever the posterior roots by avulsion of the intercostal nerves without opening the vertebral canal.

SECTION III.—*For Spasm.*

CASE 4.—The patient was a girl, aged 16 years, under the care of Dr. E. J. Toye, of Bideford. She had had spastic hemiplegia since infancy.

Condition.—May, 1910. A well-nourished and very intelligent girl, perfectly healthy except for the paretic condition. The right arm is never used, but held at the side with the forearm strongly pronated and the hand flexed. There is no muscular wasting. All active movements are clumsy and uncertain, whilst passive movements provoke a strong and painful spasm. This is particularly the case with the muscles of the hand, and any attempt to straighten the fingers or wrist causes them to be strongly flexed so that the tips of the fingers touch the front of the forearm. The movements of the right leg are much less abnormal, but there is a spastic contraction of the calf muscles which makes her walk on the toe.

First operation.— May, 1910. The median nerve was stretched above the elbow. The tendo Achillis was cut. The relief of the arm spasm was of very short duration, but the leg condition has been permanently improved.

FIG. 4.

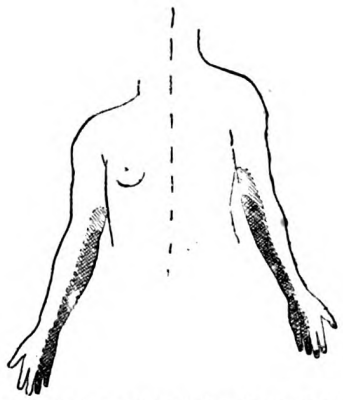


Diagram of the area of anæsthesia in Case 4 after the operation. The larger area shows the loss of pain sense.

Second operation.—Dec. 20th. Posterior root resection. The right halves of the fifth, sixth, and seventh cervical vertebræ were removed and the dura was opened. The right posterior roots of the sixth, seventh, and eighth cervical and first dorsal nerves were resected. On the following day the hand was absolutely flaccid and afforded the most convincing demonstration of the influence of posterior root resection in abolishing spasm. About a week later, although there was no return of spasm, the muscles had regained their tone, and it was evident that the long-continued contraction of the forearm muscles had caused a shortening of these relative to the length of the bones. Either the wrist or fingers could be extended separately, but not at the same time.

FIG. 5.

Reproduction of a photograph of Case 4 before operation.

Third operation.—Jan. 3rd, 1911. A portion of both radius and ulna measuring three-quarters of an inch was removed. The bones were brought together over medullary pegs without any other sutures.

Present condition (April, 1911).—The forearm is kept on a splint with the hand in a position of hyperextension and abduction. The patient has already acquired some use in the fingers, being able feebly to grasp a pen. The whole hand and fingers can be fully extended, but the thumb is still strongly adducted, owing to the shortening of its intrinsic muscles. Movements at the elbow and shoulder can be executed within a small range which is slowly increasing. Sensation is unimpaired except over an area extending along the ulnar side of the forearm, including the little and ring fingers, and reaching above the elbow for two inches. (Fig. 4.) The protopathic loss is slightly greater than the epicritic, the margin of the areas of the two forms of sensation being about one inch apart above the elbow and half an inch in the forearm.

[9] Cotte: Lyon Medicale, 106, p. 777.

CASE 5.—The patient was a single woman aged 33 years. She is said to have had "a stroke" when 15 months old, ever since which she has been weak in the left arm and leg. For some years past she has been an inmate of the workhouse and she was admitted to the Cossham Hospital in March, 1911.

Condition on admission.—Well nourished and intelligent, with no disease except spastic paresis of the left arm and leg. Slight wasting and loss of mobility on the left side of the face. Left arm: There is some general paresis affecting chiefly the muscles below the elbow. This is accompanied by spasm and coarse athetoid movements of the hand and fingers. Left leg: Slight muscular wasting below the knee; the foot is held in a position of extreme equinus, and on attempting to correct this very marked clonic contractions are set up which are very painful and make her cry. On attempting to walk the patient holds the foot in extreme plantar flexion and is often thrown to the ground by the onset of clonus. It is this liability to be thrown down that makes her unable to earn her living as a domestic servant. The left knee-jerk is much increased. Babinski's sign is absent. The whole of the left side of the trunk and limbs present a marked anæsthesia and analgesia.

Operation.—March 13th, 1911. Laminectomy of the eleventh and twelfth dorsal and first and second lumbar vertebræ; resection of the second and fourth lumbar and first and third sacral left posterior nerve roots. The blood pressure only fell from 140 to 128 mm. during the operation and there was no immediate drop after the actual division of the nerves.

FIG. 6.

Reproduction of a photograph of hand of Case 4 after operation.

After-history.—The patient made a good recovery, except for some pain in the wound and a slight attack of cystitis which followed temporary retention of urine. On March 16th the note is: "The muscular rigidity of the left leg is greatly improved, the foot can be dorsi-flexed without causing any clonus, the knee-jerk is absent." But unfortunately this improvement was only of temporary duration, and on April 25th the liability to ankle-clonus had returned. She had at that time a good deal of ataxia in the movements of the legs, which made her feel that the operation had left her worse than before. This case, though a failure from the patient's point of view, is very interesting and instructive from that of physiology. Professor Förster gives the fifth lumbar and first and second sacral nerve roots as being the segments of the cord concerned in the control of the plantar-flexors of the foot, and of these three I only divided the middle one—viz., the first sacral. This accounts, I think, for the very short duration of the relief of the spasm. The patient refused to have anything further done.

CASE 6.—A labourer, aged 48 years.

History.—The patient had been in the army and had served in Egypt. He had had a sore on the penis, but does not know whether it was followed by any other signs of syphilis. He was quite well until three years ago when he began to feel weakness in the legs and pain. Both these symptoms became steadily worse and for the last year he had been an inmate of the workhouse.

Condition.—The patient was admitted to the Cossham Hospital on March 9th, 1911. His condition was as follows. He is thin and weak, but there is no organic visceral disease. The right eye has a cataract of three years' formation, the left eye has good vision, but the pupil is small, reacting to light, but not to accommodation. All the muscles of the trunk and limbs are flabby and wasted. The left arm is very rigid, being held with the elbow flexed at a right angle. The legs are kept flexed at the hips and knee-joints and strongly adducted, so that he has to wear pads between the knees and ankles to prevent these parts becoming rubbed into sores. Any attempt at extension or abduction of the legs causes him the most intense pain. He finds that sitting in a chair is the most endurable attitude, but during the past year the pain has been so intense as to allow him but little sleep.

Operation.—March 11th, 1911. Laminectomy of the eleventh and twelfth dorsal and first and second lumbar vertebræ; resection of the first, third and fifth lumbar and first and second sacral left, and the first and fourth lumbar and first and second sacral right posterior spinal roots. The blood pressure only fell from 108 to 102 mm. during the operation and there was no noticeable drop after the actual section of the nerve roots.

After-history.—The pain and spasm have completely disappeared from both legs, from immediately after the operation until the date of the report (June, 1911). The patient has been able to sleep quietly and comfortably, and he expresses himself as greatly pleased with the relief he has been afforded. On April 23rd a tenotomy was done of both the adductors and the hamstrings on each leg, after which the limbs could be placed in a position of full extension and abduction. He can stand with crutches, but we have not yet been able to get him to walk. The wasting and paresis do not give much grounds for hope in this respect.

FIG. 7.

Reproduction of a photograph of Case 6 before operation.

I do not propose to summarise the cases published of this operation for the relief of spasm, because Professor Förster is dealing fully with this and with the other general aspects of the question. There are, however, several points of interest about the subject, suggested by the cases related that I will briefly touch upon.

FIG. 8.

Reproduction of a photograph of Case 6 after operation.

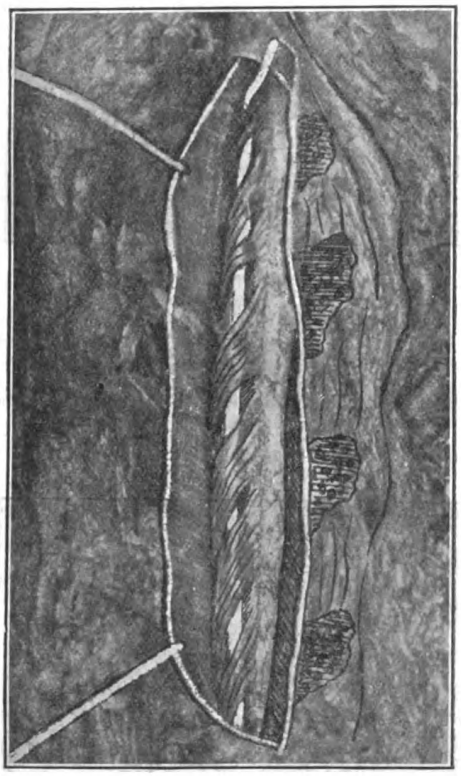
The theory upon which the operation is based.—Hitherto, as far as I am aware, there has been no definite proof as to the manner in which the division of the posterior roots diminishes the spasm emitted from the motor nerves of the same segment. Warrington's[10] experimental work, however, supplies this, and Dr. Short has demonstrated in my third case that

[10] Warrington: Journal of Physiology, xxiii., p. 112, and xxiv., p. 464.

there does occur in the anterior horn cells and in those of Clarke's column a definite chromatolysis. This change only affects a certain number of cells, and according to Warrington some of them recover their normal structure in time. We have here, therefore, a definite anatomical proof of the lessening of the motor activity in those segments where the posterior roots have been resected. In the light of this fact it may be urged that some atrophy and loss of muscular power must result from the operation. But this is shown not to be the case by such examples of the operation afforded by my first two cases, in whom all the posterior roots connected with the leg had been divided, and in whom at intervals of more than one year there is neither loss of power or bulk in the muscles.

The best method of laminectomy.—In my first case I adopted the method of an osteoplastic flap, but I think that it has no advantages which compensate for the great risk of the ill-nourished flap sloughing, and I should never attempt it again. Taylor's suggestion

FIG. 9.

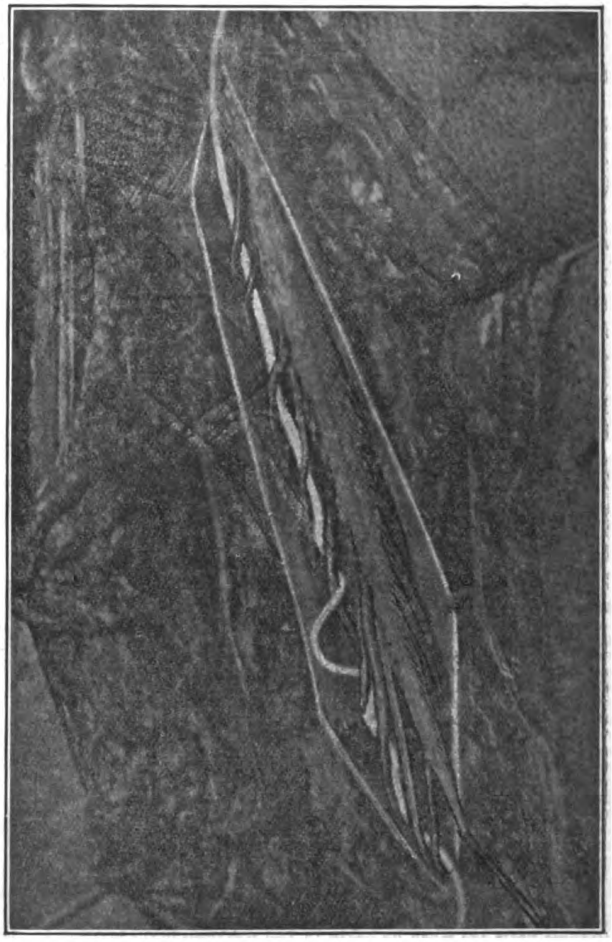


Exposure of the brachial roots by hemi-laminectomy of the fifth, sixth, and seventh cervical and first dorsal vertebræ. A white string lies behind the roots. The highest root shown is the fifth cervical, the lowest is the second dorsal.

of a hemi-laminectomy is an excellent one when applied to the cervical region. The bifid cervical spines make it quite easy of performance, the oozing surface is half that of the usual laminectomy, and the important neck muscles are only interfered with on one side. This method gives ample room for dealing with the posterior roots of both sides. In the lumbar region most of these arguments do not apply. The parts are so deeply placed that one wants all the possible lateral space, and the medianly placed muscle tendons are of not much importance.

The question of the two-stage operation.—On the continent the operation has usually been performed in two stages—the removal of the laminæ first and the opening the dura, with resection of the nerve-roots, second. I think that this is not necessary, and that its drawbacks greatly outweigh its advantages. It is designed to minimise the shock, which is supposed to be especially great in this operation. This idea arises largely from a theoretical conception that division of a number of sensory roots must cause a grave degree of shock. But when tested by observations on the blood pressure taken at frequent intervals during the operation it is found that no more effect is caused by the division of the nerve roots than by any other stage in the proceeding. In the last two cases recorded above there was no difference between the blood pressure taken just before and just after the division of the nerves. And at the end of the operation it was only a few millimetres less than at the beginning. In those cases where much shock occurs during the course of a laminectomy it is probably due to the free bleeding and to the long time taken in arresting it. If, however, a large quantity (2–3 ounces) of a 1 in 50,000 solution of adrenalin be freely injected into all the subcutaneous and muscular tissues, as suggested by Braun,[11] the operation becomes an almost bloodless one, and

FIG. 10.



Exposure of the lumbo-sacral roots by removal of the laminæ of the eleventh and twelfth dorsal, and the first and second lumbar vertebræ. A white string lies behind the roots. The highest root shown is the first lumbar, the lowest the fourth sacral. The filum terminale is held up by thread.

since I have adopted this plan (in the last three cases) I have not had to apply a single pair of pressure forceps or ligature a bleeding point. If, then, the operation can be made quick and bloodless, and if the division of the nerve roots is not productive of shock, there is left no reason for adopting the two-stage method of attack. The disadvantages of the double operation are, moreover, very great. There is much increased danger of sepsis, to which a considerable proportion of the recorded deaths have been due. After the first stage there is all the pain of an ordinary laminectomy, whilst the painful spasms or crises are much exacerbated. The risks of the

[11] Braun: Deutsche Zeitschrift für Chirurgie, 1910 . 561.

anæsthetic are doubled, and the chances of healing by first intention are diminished.

The approach to the lumbo-sacral roots.—It has usually been advised in dealing with the lumbar and sacral roots to approach them at their point of exit from the dura. But this necessitates the removal of all the lumbar vertebral laminæ. These, on account of their size, their depth, and the thickness of the muscles covering them, are the most difficult to remove. It seems to me that it is much simpler and easier to attack the lower roots at the point where they all lie close together at their origin from the spinal cord. This necessitates a smaller removal of laminæ, because the roots lie crowded close together instead of far apart. It is quite sufficient to take away the laminæ of the eleventh and twelfth dorsal and the first and second lumbar vertebræ to fully expose and resect all the lumbar and sacral roots. The incision is placed higher up in the back in a situation where it is in less danger of being fouled by urine or infected from a bed-sore. The differentiation between the anterior and the posterior roots is much easier at the level of the cord than at the exit from the dura. The only disadvantage of the high attack of the roots is the increased difficulty of identifying the various nerves. This may be overcome by observing that the third sacral root is the last root of any size to be given off from the conus medullaris. This never need be cut for the relief of spasm of the leg muscles because it is associated with the buttocks and perineum only. The root above it—viz., the second sacral—is the first to be divided, and then each alternate root is removed. So long as a good half of the afferent roots in the lumbar and sacral regions are divided the object of the operation is fulfilled, irrespectively of the exact nerves cut. In certain cases—e.g., my fifth case—where the main complaint is due to spasm of a single group of muscles, it would be better, I think, to divide all the posterior roots concerned with that group rather than to take alternate nerves. It was because I failed to do this that the result in the case I refer to was so poor.

The relation of orthopædic operations to nerve-root division.—Professor Förster has so clearly indicated the general rules for the selection of cases of spasm suitable for the operation that I will only refer to one point. It has been suggested by some, especially by Biesalski,[12] that the nerve operation should not be done until every possible attempt has been made by tenotomies and other orthopædic operations to correct the deformities. There are, of course, some slight cases where a simple tenotomy will give great relief, but when there is that excessive spasm which ties up a whole limb in a complicated deformity it seems to me to be useless to expect any good at all from orthopædic operations whilst the spasm remains unabated. Both weight extension and splint treatment are very badly tolerated by patients in whom there is active or painful spasm, whereas if this spasm be first abolished by the nerve operation the ideal conditions of muscular flaccidity and freedom from pain are provided which are so necessary for the correction of deformities.

I would briefly summarise my conclusions as follows:—

1. For the relief of pain the operation of posterior nerve-root resection is a somewhat uncertain proceeding. Cases which present very great pain without any organic disease are often of a highly neurotic temperament, and their pain seems to have an important psychical element which is not relieved by the operation.

2. For the relief of visceral crises the operation holds out the only prospect of radical cure which we know of at present. Only those cases of this kind are suitable in which all other means of relief have failed, but on the other hand it is important not to wait until the patient has become debilitated by emaciation and morphia.

3. In cases of spasm associated with lesions of the pyramidal tract the operation has its largest field of usefulness. Spasm is in all these cases definitely relieved, and if the pyramidal tract is not wholly severed a great improvement of motility results.

4. The operation causes definite chromatolysis of some of the motor cells in the anterior horn of the segments involved, and this is probably associated with the lessening of motor spasm.

5. By the use of adrenalin injections as a preliminary to the operation the procedure becomes an almost bloodless and speedy one.

6. There is no special shock associated with the division of the posterior nerve roots.

7. It is better to perform the whole operation in one stage.

8. In dealing with the brachial roots it is best to do a hemi-laminectomy.

9. The lumbo-sacral roots are best approached at their junction with the cord rather than at their point of exit from the dura.

In conclusion, I would express my most sincere thanks to Professor Förster for the inspiration of his work and writings, and especially for his kindness in coming over to London to explain his views and to demonstrate the brilliant results which have been achieved by his initiative. I have also to thank most cordially Dr. A. R. Short for his elucidation of the pathological part of my paper, and Mr. Jackson Taylor for the photographs and slides of the cases which were under his care as my house surgeon.

NOTE ON THREE CASES OF FIBROID TUMOUR OF THE UTERUS SPONTANEOUSLY FATAL.

BY ARTHUR H. N. LEWERS, M.D. LOND., F.R.C.P. LOND.,

SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

IN considering the line of treatment to be adopted in cases of uterine fibroids, it should be borne in mind that although, as a rule, these tumours for the most part grow slowly, there may, nevertheless, even after many years of quiescence, come an acute or subacute stage which may have a fatal termination, as in the cases here recorded. The life-history of these growths may extend over many years; therefore, if left to run their natural course, it rarely happens that one observer can see the whole progress of a case of fibroids from the time when the tumours are first recognised, or first produce symptoms, to the end of the case, apart from operation.

While, as has been said, fibroids, on the whole, are characterised by slow growth, often with intervals during which they appear to be stationary, they may at times take on changes, whether of degeneration and infection, or of growth, which rapidly cause acute symptoms, and may put the patient's life in jeopardy. Such an acute crisis may easily happen in a patient known to have had fibroids for many years, but it is quite likely that when the acute crisis does occur she may not come under the observation of the practitioner, or practitioners, who have seen her during the earlier period of the case. Those who have happened to have seen the case only during its quiescent and apparently harmless phases may never know what the termination has been, and if they happen to bear the case in remembrance at all may think of it as an example of the satisfactory results of expectant treatment.

Reflections of this kind are suggested by such cases as the three about to be recorded. In each of them the tumours must have been present for many years, and during the greater part of the time presumably symptoms were either absent or slight. Similarly, during the greater part of the time the general health was not seriously affected, and the tumours might no doubt have been removed at a very slight risk. While I do not advocate removing fibroids of the uterus when they are really small, and causing no symptoms, I do think that once they have reached a size equal to that of the pregnant uterus at the end of the third month, for instance, even apart from any marked symptoms, it is safer for the patient to have the growths removed. The popular impression that these tumours may be expected to give no trouble after the menopause is certainly often wrong. Quite recently, for instance, a patient, 65 years of age, was admitted under my care into the London Hospital suffering from metrorrhagia and other symptoms. On dilating the cervix a submucous fibroid of the size of an orange was found in the uterine cavity. It was removed by cutting it away piecemeal,

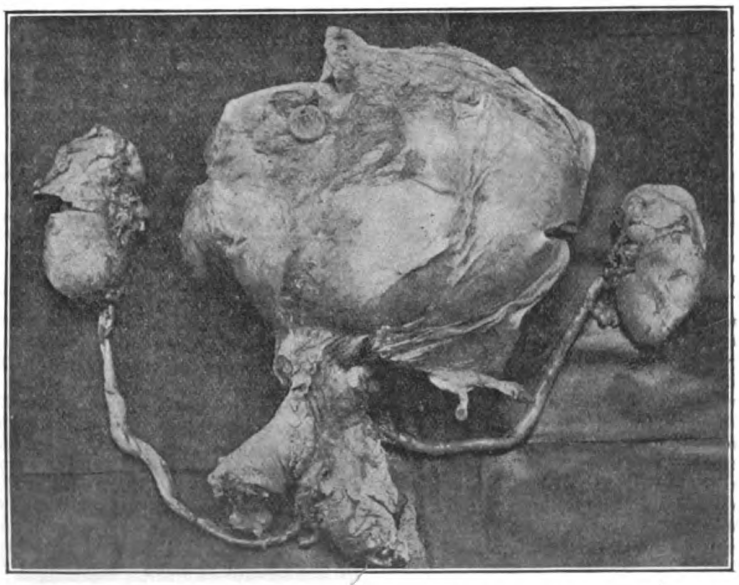
and the patient did well. I have seen many other cases where serious symptoms have been caused by fibroids long after the menopause.

CASE 1. *Case of fibroid spontaneously fatal from hæmorrhage.*—The patient was a married woman, aged 47, who had had three children, the last in 1895, and who was admitted under my care into the London Hospital on April 4th, 1908. Up to two years previously the catamenia had been regular and normal; since that time the periods had been more frequent and profuse. The patient was admitted from the out-patient department, where she had come complaining of flooding and fainting attacks for the previous three days. During vaginal examination in the out-patient department a severe hæmorrhage occurred, necessitating immediate plugging of the vagina with gauze before the patient could be removed into the wards, where she was admitted at 4 P.M. At 8 P.M. on the same night the gauze plugging was gently removed. A fresh alarming hæmorrhage started. The vagina was again plugged, but the patient never recovered from the effects of this hæmorrhage; she shortly became delirious and died from gradual heart failure secondary to the hæmorrhage on April 8th. As regards the treatment adopted after her admission, saline injections per rectum were given freely, but they proved useless.

FIG. 1.

Fibroid polyp springing from anterior lip of cervix. Fatal hæmorrhage. Vagina opened posteriorly. Case 1.

FIG. 2.



Fibroid of anterior wall of uterus and cervix. Ureters dilated by pressure. Severe hæmorrhage; sudden death, probably partly due to uræmia. Case 3.

Post-mortem examination. — The pelvic cavity is occupied by a smooth rounded mass 4 inches in diameter lying below and in front of the uterus, and springing by a pedicle from the anterior lip of the cervix (Fig. 1). The bladder is pushed upwards and forwards; it is flattened from side to side and the posterior wall is bulged forward; the rectum is similarly compressed, and its anterior wall is pushed back. Vagina: On opening the vagina a large mass is seen distending it, having a diameter of 4 inches. High up posteriorly is seen the external os, the posterior lip of the cervix being thin and crescentic. On section, the tumour shows well-defined white fibrous strands and reddish-brown areas enclosed between them. A capsule is distinctly seen loosely attached to the surface of the tumour. At its lower vaginal pole the capsule shows several small ulcerated areas, which have encroached on the venous sinuses of the capsule. Numerous thrombi occupy those ulcerated patches, which have evidently been the source of the hæmorrhage. There is no marked myocardial degeneration, in spite of the grave general anæmia. With the exception of œdema of the lower lobes of the lungs and some muco-purulent secretion in the bronchioles, there are no other outstanding pathological lesions of importance.

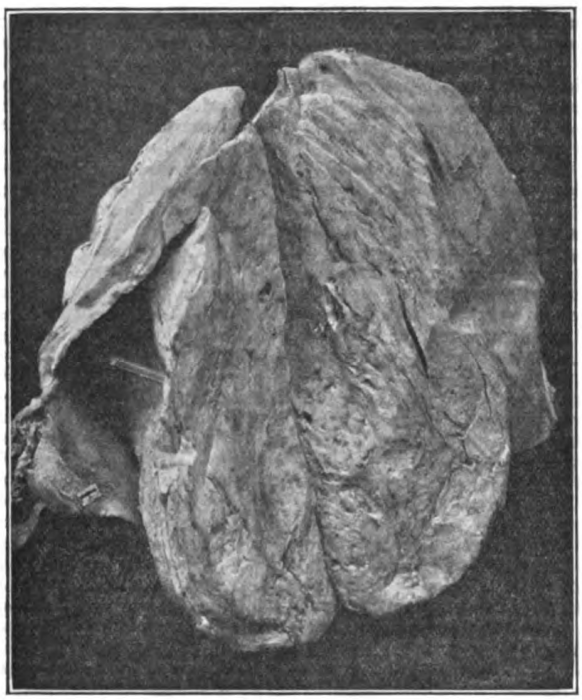
CASE 2. *Case of fibroid spontaneously fatal from pulmonary embolism.* — The patient, a single woman, aged 42, was admitted into the London Hospital under my care on June 25th, 1909. She complained of a lump in the abdomen which she had noticed for 18 months, and which had been slowly growing; also of micturition being frequent, and on two occasions there had been actual retention. There was said to have been no menorrhagia. The patient was somewhat anæmic. On examination there was a firm median swelling in the hypogastric region, which could not be separated from the uterus on bimanual examination, and was taken to be the uterus enlarged by fibroids. The patient seemed to be in fair general health on admission, except for the slight anæmia and the presence of the tumour. On the day following admission she was said to have had a kind of "fit." She became suddenly rigid and cyanosed, and fell back dead. She was quietly reading in bed at the time when the seizure occurred.

Post-mortem examination. — This showed the uterus to be considerably enlarged by an interstitial fibroid in the anterior wall forming the hypogastric "tumour" found on examination. It measured 7 inches in diameter and had a circumference of 20 inches. The fibroid was soft and of a beefy-red colour, an example of "red" degeneration. The cause of death was found to have been pulmonary embolism, A laminated friable clot, 2 inches in length, was found blocking the pulmonary artery at its bifurcation and extending a short way along the left pulmonary artery. The clot was found to have originated on a valve at the end of the left iliac vein, where an adherent grey clot was found filling the lumen of the vessel and extending a quarter of an

inch in the direction of the blood stream. Both ureters were dilated so as to be half an inch in diameter. The pelvis of each kidney was also largely dilated.

CASE 3. *Case of large interstitial fibroid of the uterus; sudden collapse, heart failure, and death.*—The patient, a widow, aged 41, was admitted under my colleague, Dr. F. J. Smith, on the morning of Jan. 28th, 1910. She had had one child eight years ago. History: She had had a severe flooding in June, 1909, and bleeding had continued on and off, clots occasionally being passed, till Jan. 24th, 1910. On this day, while at the sewing-machine, a severe flooding came on. The medical man who was sent for to see her advised her immediate removal to the London Hospital. On admission she was very much collapsed, but was temporarily revived by saline injections and strychnine hypodermically. A catheter specimen of the urine was examined, and contained no albumen. On the afternoon of the 28th I was asked to see her. She was so much collapsed that anything like a complete examination of the case was impossible, but a large tumour was noticed in the abdomen reaching considerably above the umbilicus. She was transferred to the gynæcological ward at 7.45 P.M. on the same evening. The pulse then was very weak and running. She was profoundly anæmic, and respiration was sighing. At 8.30 her condition became very much worse, and her pulse was then uncountable. She was treated with saline injections per rectum, also with coffee and brandy per rectum, but she died on the same evening. No hæmorrhage had occurred since her admission into the hospital.

FIG. 3.



Uterus opened, showing fibroid (in section) springing from anterior wall of uterus and cervix. Uterine cavity seen to the left was seven inches long. Case 3.

Post-mortem examination.—A large fibroid tumour lies in the anterior wall of the uterus and cervix; its lower pole is impacted in the pelvis, its upper pole rises several inches above the umbilicus; the terminal two inches of each ureter are seen firmly compressed between the fibroid behind and the bony wall of pelvis in front. (Figs. 2 and 3.) Above this point the ureters are tortuous, and dilated to the calibre of the forefinger. The pelves of both kidneys are thin and dilated, and both kidneys are hydronephrotic. There are extreme anæmia and œdema of both kidneys. The bladder is very slightly dilated; its base is thin. The majority of the muscle is drawn up and retracted to the fundus of the bladder. The ureters are easily canalised at their terminal portions by a fairly large probe. On the left side there is a small hæmatosalpinx. The right and left ovaries are atrophied, with a small hæmorrhagic cyst in the left ovary. There are some chronic fibrotic tubercles in both apices with caseous nodules; fibrous adhesions are present over the whole of the left lung and at the right apex. There are anæmia and œdema of all the organs.

Upper Brook-street, W.

THE THERAPEUTIC EFFECTS OF CARBON DIOXIDE SNOW. METHODS OF COLLECTING AND APPLYING IT.

BY J. HALL-EDWARDS, L.R.C.P. EDIN., HON. F.R.P.S.,
SENIOR OFFICER IN CHARGE OF THE X RAY DEPARTMENT AT THE GENERAL HOSPITAL, BIRMINGHAM.

FOR some years liquid air has been used as a local destructive agent by dermatologists, especially in America. The possibility of using it with good effect in surgery early presented itself to the minds of many surgeons who were aware of its properties, but until within the last few years the difficulty of obtaining and transporting it has stood in the way of its general use. It has been successfully used in the treatment of warts, nævi, and angiomata, also in cases of lupus vulgaris, chronic eczema, and lichen planus. Owing to the great rapidity with which liquid air evaporates when exposed to the atmosphere it can be carried about only in especially constructed vessels which cannot be corked or stoppered or they would burst from the internal pressure set up in them. These vessels, the walls of which are composed of two thicknesses of glass with a space between them from which the air has been exhausted, are known as Dewar's or, more popularly, Thermos flasks. The liquid is difficult to apply to small areas, and considerable skill and practice are necessary to limit its effects to the area required. It produces an intense cold, reaching as low as 120° C. below zero. It was first used in this country by the late Dr. Radcliffe Crocker, who published details of a large number of cases which he had treated with excellent results.

In 1908 Dr. Allen Pusey, of Chicago, suggested the use of carbon dioxide snow in its place, as being far more easily manipulated and applied. The fact that the temperature of the snow is nothing like so low as that of liquid air, coupled with the fact that it can be collected with ease and carried about with little trouble, should commend it to those who require such an agent. With the snow properly prepared a temperature of 79° C. below zero can be obtained. This temperature is sufficiently low for the majority of cases. It has been found a very valuable local destructive agent, and has been applied in a large number of dermatological conditions with good effect. The chief merit of carbon dioxide snow lies in the fact that the materials and apparatus for preparing, collecting, and applying it can be always kept ready at hand, whilst its preparation occupies but a few minutes and its cost is small. The principle involved in its use is that of destroying the tissue cells by freezing, the effects being attributed to the exceedingly low temperature obtained. It is said that carbon dioxide has no local action of its own. The freezing of the skin gives very little pain, certainly not more than can be borne by the average individual, and frequently children bear it without complaint. The immediate effect of the application of the snow is the formation of a hard, white area, corresponding in size to the piece of compressed snow applied. This area is, as

a rule, depressed below that of the surrounding skin, the amount of depression corresponding with the amount of pressure used in its application and the elasticity of the tissues to which it is applied. The time usually occupied in the application of the snow depends upon the nature and position of the lesion attacked, and may vary from five seconds to a minute, or even more. In very superficial nævi from five to 20 seconds is usually sufficient, the time depending on the age of the patient and on the sensitiveness of the skin. Great care must be taken not to administer an overdose, and special care must be exercised when dealing with lesions upon the skins of babies and young children. In very superficial nævi the exposure must be short and the pressure slight. It is far better to administer a too short application than an overdose, as the applications can always be repeated if the desired effect is not attained on the first occasion. In deeper forms of lesions the applications may last as long as 40 seconds, and in treating corns and large warts, even after the greater portion of the hardened skin has been cut away, the applications may extend to over a minute. Great care must be exercised in deciding not only the length of the application but the amount of pressure necessary to bring about the desired result. Over-exposure may result in the formation of an ulcer which may leave a permanent and ugly scar, and great damage may be done by overstepping the bounds in either the length of the application or the amount of pressure used. The scar, after a successful treatment, is, as a rule, fine, colourless, and soft. In superficial lesions the scar becomes almost invisible after a few months, but in deep ones it can be slightly seen throughout life, but even under the most adverse conditions the scar is a better one than is formed by any other method with, perhaps, the exception of radium. Excellent results are obtained by this method of treatment in pigmented stellate and capillary nævi. In pigmented nævi a well-nigh perfect result can be obtained. In such cases it is far superior to radium, which appears to have no effect upon the pigment itself. This, however, totally disappears under the influence of the snow. In pigmented hairy nævi and raised angiomata several applications are usually necessary, and although the results are no better than those obtained with radium, the time occupied in obtaining them is shorter and the cost infinitely less. Carbon dioxide snow has been used with marked success in old-standing cases of lupus vulgaris which have ceased to respond to the action of the Roentgen rays, and in some cases of lupus erythematosus excellent results are obtained. In cases of large port-wine stains and moles, where many applications would have to be made, Dr. J. L. Bunch states that liquid air is far more satisfactory than snow.

It is exceedingly difficult to formulate rules as a guide to the length of exposure which should be given and the amount of pressure which should be used in any given case. Dr. Reginald Morton advises that in the treatment of a vascular growth the pressure should be sufficient to arrest the circulation.[1] "The depth to which the freezing action extends is a question of pressure and of the time it is kept up. Where the bone is near the surface it is quite easy to freeze the soft tissues to it. This often happens when treating nævi of the scalp, and such cases do very well on account of its being quite easy to carry out the freezing process quite completely." Immediately after thawing, which process takes far longer than the freezing, there is little difference to be noticed with the exception of a slight reddening, but reaction soon makes itself manifest. Within a few minutes the tissues become firm to the touch and begin to swell and a wheal forms. A vesicle nearly always follows an application of more than 15 seconds, and generally makes its appearance in from one to three hours' time. It is well in most cases to puncture this with a sterile needle, after which it should be dressed with some antiseptic ointment. In from four to five days after a successful application a scab should form, which, unless there be pus underneath, should be allowed to come off of its own accord. No necrosis or sloughing should follow an application properly administered. Necrosis, however, can be brought about by repeated applications given at short intervals.

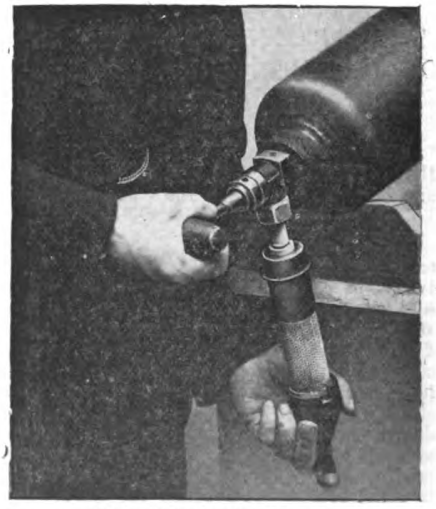
One of the chief advantages of treatment by means of carbon dioxide snow is the painlessness of the process; it is unnecessary in by far the larger majority of cases to administer an anæsthetic. Carbon dioxide snow can be used with good effect in most of the superficial lesions in which radium is used, and it has the advantage of being far less costly and of occupying far less time in producing its results. It is much more easy to apply to young children, with whom there is always a difficulty in keeping the radium applicator in position.

The field of usefulness of this new agent is as yet not completely explored. Some cases of small rodent ulcer have been treated, but some time must elapse before we shall be in a position to say whether in such cases it is as good as, or superior to, the older methods. That its field of usefulness is limited is certain, but inasmuch as it places in our hands a well-nigh painless method of dealing with some of the pre-cancerous conditions which exist in parts of the body inaccessible to the surgeon, it bids fair to take its place as an exceedingly useful agent in the relief of suffering.

On the occasion of my first introduction to carbon dioxide snow I was struck by the crudity and wasteful method of collecting it, and with the object of overcoming these difficulties I designed a collector and applicators, which I think have distinct advantages over the usual methods employed. My collector not only admits of the obtaining of the small and necessary amount of snow for one treatment without waste, but it renders it unnecessary to transfer the snow from one piece of apparatus to another, a compressed tablet being produced with the greatest ease in two or three minutes. My collector consists of a tube formed from a sheet of perforated zinc or tin, inside which is a tube of copperwire gauze, whilst between the two is a layer of soft material composed of felt, &c. The complete tube, about 8 inches in length and 2 inches in diameter, is furnished at its upper end with a brass mount or ring, which is slightly tapered internally. At its lower end is attached a vulcanite tube which constitutes a mould for compressing the snow into tablets. The open lower end of this mould is stopped during the collection of the snow by means of a vulcanite plug. To the nozzle of the gas bottle is attached a tube provided with a tapered brass plug which fits accurately the brass ring at the upper end of the collector. To obtain the snow the collector is held firmly in contact with the tapered brass plug, whilst with the other hand the bottle valve is gently opened by means of a key.

During the collection of the snow the gas bottle should be held upside down, or, if this is impracticable, it should be tipped to an angle of 45°. (Fig. 1.) The attempt to collect with the bottle in the upright position ends in disappointment and in enormous waste of gas. I have recently improved the collector by covering the perforated zinc with a sleeve or tube of thick leather in which a small hole, an eighth of an inch in diameter, is punched through at its lower end. This

FIG. 1.

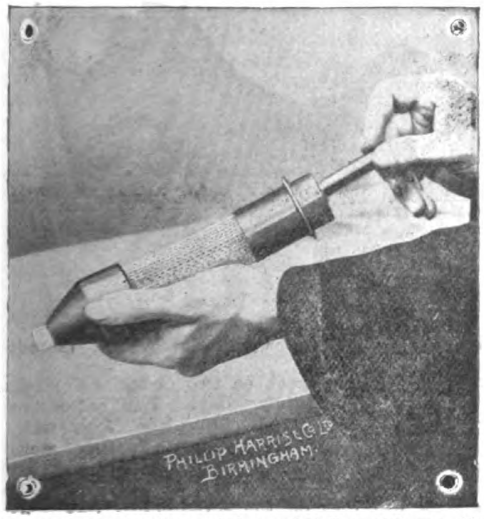


Method of collecting CO_2 snow.

[1] The Use of Carbon Dioxide in Dermatology, by Edward Reginald Morton, M.D., F.R.C.S., Brit. Med. Jour., Sept. 24th, 1910. THE LANCET, August 20th, 1910, p. 559.

improvement allows of very little waste of gas, and in addition it enables the collector to be handled freely without freezing the fingers. When a sufficient quantity of snow is gathered in the collector a long wooden or vulcanite rod which accurately fits the lower end of the apparatus is passed down its centre. The snow is detached from the sides of the collector and falls into the vulcanite mould, where it is compressed between the end of the rod and the plug, with which, as I have previously mentioned, the lower end of the apparatus is closed. The plug is now removed, and by means of the rod the compressed tablet is pushed through the lower orifice. (Fig. 2.)

FIG. 2.



Compressed tablet of snow being pushed through lower orifice.

If a second tablet is required the plug is again placed into position, more snow is detached from the sides of the collector, and the operation of compression is repeated. It is best to make the tablets from a quarter to half an inch in thickness;

FIG. 3. FIG. 3A.

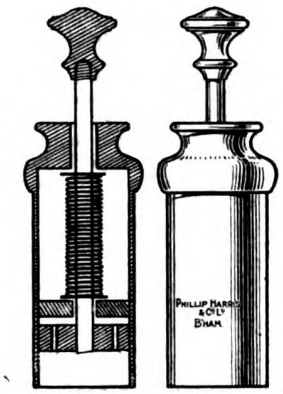
Screw clamp containing collector and plunger. Cone-shaped tablet held in applicator.

their degree of hardness can be regulated by the amount of compression used in their manufacture. When the collector is well filled from four to six such tablets can be made in rapid succession.

Many surgeons prefer to use the snow much more firmly compressed than it is possible to make it by hand pressure alone. To facilitate the obtaining of this I have devised a special screw-clamp (Fig. 3), into which the collector and plunger can be placed, and pressure can be brought upon the tablet by means of a hand-screw. By this means a tablet can be prepared which is of greater hardness, is nearly transparent, and sinks in water. In preparing such a tablet it is necessary that much more snow be used, and only one such tablet can be prepared at a time. As, owing to their hardness, these compressed tablets can be cut up with difficulty, I have devised a method whereby circular surfaces varying from an eighth of an inch to one inch in diameter can be obtained with ease. For this purpose a second plug is required. This plug is hollowed out into the shape of a cone, so that the tablet when prepared consists of a cylinder of compressed snow of from one-half to an inch in length, with a cone-shaped projection of about the same length. By cutting off with a knife a piece of this cone it will be seen that a surface of any desired diameter can be obtained. Fig. 3A shows the cone-shaped tablet held in the applicator which I will shortly describe.

The chief difficulty which confronts the surgeon in the application of carbon dioxide snow is that of firmly holding the snow and of regulating the pressure necessary to produce the desired result. To overcome this difficulty I have designed an applicator which is easy to handle and effective in use The instrument is made of vulcanite, with the exception of the piston which carries the plunger, the collar which guides it, and the spring which keeps it in position. It consists of a tube of vulcanite, the lower edge of which is bevelled, so as to form a thin edge, and a plunger which is held up by a spring at a distance of about a quarter of an inch from the end of the tube. The plunger is perforated so as to allow of the escape of gas, and thus prevent the tablet from being forced out. Pressure on the knob of the piston allows of the plunger being pushed down until it is level with the end of the tube. The sectional drawing, Fig. 4, shows

FIG. 4.



Vulcanite applicator.

clearly the arrangement. The applicators are made in three sizes. No. 1 holds the full size tablet, as produced by the collector, and is slightly more than an inch in diameter. This applicator is the only one which will hold the hard compressed cone-shaped tablet before mentioned, and is figured in Fig. 3A. Applicator No. 2 is half an inch in diameter, and No. 3 a quarter of an inch. To load the applicator the open end is pressed upon a tablet on a flat surface, when it either takes up the whole of it, or (in case of the softer ones) cuts out a circle of the desired size. The snow not used is returned to the collector. It will be seen that with this apparatus carbon dioxide snow of various degrees of compression can be prepared at will. Some surgeons prefer the hard tablets, others the softer ones. In applying the snow the applicator is held in the right hand in the same way as a hypodermic syringe is held, the necessary pressure being made with the thumb placed upon the knob of the plunger.

If after preparing a hard compressed tablet the apparatus be left clamped up the snow will keep for a considerable

time, and the whole apparatus can be carried in a handbag for some distance without its being necessary to cart about a cumbersome and heavy gas bottle.

The whole apparatus above described has been made at my suggestion by Messrs. Philip Harris and Co., Limited, of Birmingham, whom I have to thank for the care and trouble exercised in carrying out my ideas.

Birmingham.

THREE CASES OF TOOTH-PLATE IMPACTED IN THE ŒSOPHAGUS AND PHARYNX;

WITH SPECIAL REFERENCE TO THE OPERATION OF ŒSOPHAGOTOMY.

BY LIONEL E. C. NORBURY, M.B., B.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE BELGRAVE HOSPITAL FOR CHILDREN; LATE RESIDENT ASSISTANT SURGEON, ST. THOMAS'S HOSPITAL.

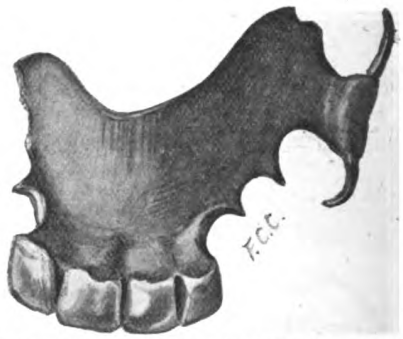
THE following cases were admitted to St. Thomas's Hospital within a few months of each other, under the care of Mr. C. A. Ballance, to whom I am greatly indebted for his kindness in allowing me to operate upon and otherwise treat the patients, and also for permission to make use of the clinical notes.

CASE 1.—The patient, a man, aged 45 years, was admitted on March 3rd, 1910, with the history of having swallowed his tooth-plate during sleep a short time previously. He complained of great discomfort and irritation in the throat; the act of swallowing was exceedingly painful; coughing was frequent, but there was no dyspnœa. A finger in the mouth could detect nothing abnormal, but on external examination a hard mass could be felt about the level of the isthmus of the thyroid. Under chloroform anæsthesia, some four hours after the accident, a finger in the mouth was unable to reach the foreign body, but it could be grasped by long œsophageal forceps. Gentle traction would not dislodge the plate. As it was known to possess some sharp hooks it was thought that these had probably become engaged in the œsophageal wall, and so further internal manipulation was deemed unsafe.

Accordingly, with the neck extended and the head turned towards the right shoulder, an incision was made along the anterior border of the left sterno-mastoid muscle, starting above at the level of the upper border of the thyroid cartilage, and was continued downwards for some four and a half inches. The platysma was divided and the sterno-mastoid retracted outwards and backwards. The omo-hyoid muscle was divided, as was also the anterior jugular vein. The sterno-hyoid and sterno-thyroid muscles, together with the lateral lobe of the thyroid gland, were displaced towards the mid-line, and the carotid sheath with its contents was displaced outwards and backwards. The plate could be felt through the œsophageal wall just below the level of the cricoid cartilage. The œsophagus was easily defined, but the recurrent laryngeal nerve was not seen. A vertical incision was made towards the posterior aspect of the œsophagus and over the underlying plate. The latter was found to be firmly fixed by its hooks to the œsophageal wall, and great difficulty was experienced in its removal. It was found necessary to enlarge the incision in the œsophagus considerably (some three inches in all) before the plate could be extricated. The plate, as shown in Fig. 1, was a large one, bearing four teeth and possessing two formidable hooks. There was very little hæmorrhage. The incision in the œsophagus was closed by two layers of catgut sutures, the first taking up the mucous membrane and the second the muscular coats. The pretracheal layer of fascia was also sutured, leaving room, however, for a small rubber drainage-tube, which reached as far as the line of incision in the œsophagus at its lowest extremity. The ends of the divided omo-hyoid muscle were united with catgut, and the skin incision was closed with silkworm-gut sutures.

As regards the after-treatment of the case, the patient was propped up in bed, a tent and steam-kettle were employed, and menthol inhalations were frequently administered. For the first six days alternate rectal feeds and saline were given, the patient only being allowed to suck formamint lozenges and acidulated tablets, which had the desired effect of relieving thirst, and which, together with menthol inhalations, kept the mouth clean and moist. Fluids by the mouth were withheld until the seventh day. The wound in the neck was dressed with gauze wrung out in 1 in 60 carbolic lotion. The drainage-tube was removed on the fourth day after operation and the stitches on the ninth day. By this time the wound had almost healed, except in the position previously occupied by the drainage-tube, in which situation there was a certain amount of leakage when fluids were swallowed. At this stage the patient was noticed to be jaundiced, the sclerotics especially being deeply tinged. On the tenth day very smart hæmorrhage occurred

FIG. 1.



Tooth-plate removed by œsophagotomy in Case 1. (Actual size.

from the wound in the neck on two occasions and again on three occasions the following day. The patient was left very weak as the result. Rectal saline, &c., were again resorted to for 48 hours. There was no further hæmorrhage and so food was then given by the mouth and gradually increased, soft-boiled eggs being allowed on the fifteenth day and a fish diet on the seventeenth day. Jaundice became less marked after the hæmorrhage, and by the thirteenth day was scarcely perceptible. The patient got up on the seventeenth day and left for a convalescent home on the twenty-second day after operation. On discharge he was able to swallow solid food without any discomfort and the wound had quite healed except for a small amount of discharge from the place where the drainage-tube had been. I saw the patient again some three weeks later. He was looking very well, the wound in the neck had quite healed, and he experienced no discomfort at all in swallowing. I have quite recently heard from him that he is in perfect health.

CASE 2.—The patient, a man, aged 50 years, of very feeble constitution, very deaf, and subject to epileptic fits, was admitted on April 27th, 1910. The history given was that a portion of his tooth-plate had a few hours previously become dislodged and swallowed during a fit. The patient complained of great difficulty and pain in swallowing. There was no dyspnœa. No foreign body could be palpated either

FIG. 2.

Tooth-plate removed by œsophagotomy in Case 2. (Actual size.)

by internal or external examination. An X ray examination revealed the presence of the plate, vertically placed and situated towards the upper end of the œsophagus. Under chloroform anæsthesia attempts to remove the plate through the mouth failed, after 15 minutes' trial. Œsophageal forceps could detect its presence, but it could not be withdrawn. Œsophagotomy was accordingly performed in a similar manner to that adopted in the previous case. In this instance, however, the recurrent laryngeal nerve was seen, and

gently drawn backwards and protected. The foreign body could be detected through the œsophageal wall, a short distance above the sternum. An incision was made just above this situation, and the plate was removed. In this case also hæmorrhage was very slight. The foreign body was a portion of a broken tooth-plate; it carried four teeth and presented several sharp jagged projections (Fig. 2). The incision in the œsophagus was closed by two layers of continuous catgut sutures, the first for the mucous membrane and the second for the muscular coats. A superimposed layer of interrupted catgut sutures through the muscular coats was also employed for extra protection. The divided pre-tracheal layer of cervical fascia was sutured, leaving room, however, for a drainage-tube down to the line of incision in the œsophagus, as in the preceding case.

On the first day after operation the temperature rose to 101·4° F., and remained high until the fifth day, when it fell to normal; slight rises for a few days followed. The patient was propped up in bed and supplied with a tent and steam-kettle. Menthol inhalations were also frequently administered. Rectal alimentation was employed for the first three days, acidulated tablets only being allowed by the mouth, which was frequently cleansed. On the third day subcutaneous emphysema was noticed on both sides of the neck, extending as low as the second rib on either side. This persisted altogether for about a week, gradually disappearing and causing no trouble to the patient. Fluids by the mouth were given on the fourth day, and slight leakage from the wound occurred. The drainage-tube was discarded. The patient was very anxious to be allowed to get up, and permission was given on the seventh day. The gratification of this wish, together with the gift of an ear-trumpet, went a long way, I feel sure, towards his recovery. The stitches were removed on the ninth day, and the wound had healed except in the position of the drainage-tube. Subsequent recovery was uninterrupted, the patient leaving hospital on the twenty-first day, able to swallow perfectly and only troubled by the presence of a very small amount of discharge from the wound in his neck. Seen some weeks later the patient was looking very well, the wound had quite healed, and he experienced no discomfort at all on deglutition. I have quite recently heard from him, in reply to a letter of mine concerning his present condition. He says that he experiences no difficulty in swallowing, the wound is quite sound, and that he eats well in spite of the fact that he has discarded his tooth-plates.

CASE 3.—The patient, a man, aged 34 years, the subject of epileptic fits, two or three occurring weekly, was admitted on Nov. 13th, 1910, with a history of having swallowed his tooth-plate during sleep five hours previously; as to whether he was suffering from a fit at the time is doubtful. The plate was one from the upper jaw, bearing two teeth on the right side and four teeth on the left side; it also possessed one sharp projection in the mid-line anteriorly. There was no dyspnœa, but the patient had considerable difficulty in swallowing. Examination under chloroform anæsthesia revealed the presence of the plate in the pharynx, its sharp projecting portion having become fixed in the epiglottis. The plate was disimpacted and extricated through the mouth by means of œsophageal forceps. The patient left hospital on the following day.

The operation of cervical œsophagotomy for removal of foreign bodies impacted in the œsophagus is one which, happily, it is not often necessary to perform, for the reason that the greater number of such accidents occur in children, where the foreign body is usually of the nature of a coin or a body with smooth and regular surfaces. Such obstacles, as a rule, can be extricated by means of the coin-catcher, or, preferably, removed by direct œsophagoscopy. There is no doubt that in employing the coin-catcher one is working in the dark, and on several occasions I have found great difficulty in extracting the coin-catcher itself, with or without the coin, the beak of this instrument having a habit of becoming impacted somewhere in the region of the upper extremity of the œsophagus.

I think it will be agreed that the scientific method of dealing with such a foreign body nowadays is by obtaining a view of it by means of the œsophagoscope, and so attempting its removal *in situ*. Removal by œsophagoscopy is, however, contra-indicated when the foreign body, as shown by the X rays or seen by means of an œsophagoscope, is large and irregular, since removal by forceps in such a case may result in laceration of the œsophageal wall, and may lead to cervical or mediastinal cellulitis. Nevertheless, it may be possible and advisable even with certain large foreign bodies, if regular in outline, to effect division *in situ* and then undertake removal of the portions by direct œsophagoscopy. When signs of perforation of the œsophagus are already present, as shown by subcutaneous emphysema, cellulitis of the neck, &c., in such cases attempted removal by œsophageal forceps, with or without œsophagoscopy, is certainly contra-indicated, and œsophagotomy is urgently called for.

In adults the commonest form of foreign body to become impacted in the œsophagus is a tooth-plate, and since such plates are often irregular in outline, possessing sharp hooks in many cases, for successful removal œosophagotomy is usually indicated. These tooth-plates are generally swallowed during sleep or while the patient is having a fit. Before deciding to open the œsophagus in such a case some indication as to the shape and size of the plate may be obtained by interrogating the patient. External palpation may disclose its presence, a view of it may be possible by direct œsophagoscopy, or œsophageal forceps may detect it. Further, the position, size, and shape of the tooth-plate may be ascertained by means of a skiagram. It may be possible to remove small tooth-plates which do not possess sharp hooks through the mouth with the aid of an œsophagoscope, either *in toto* or, if necessary, after division with some suitable instrument. If such attempts fail, however, œsophagotomy should be promptly undertaken.

Killian[1] states that in his experience foreign bodies, if they become impacted, are usually retained close to the upper end of the œsophagus. Should such a body pass the upper orifice of the œsophagus it will usually traverse the mediastinal portion of the tube, but may, however, become fixed within two inches of the cardiac orifice. With regard to the question as to how low down in the œsophagus a foreign body can be extracted by cervical œsophagotomy, Jacobson[2] points out that the most accessible portion of the œsophagus is at its junction with the pharynx, opposite the cricoid cartilage, and for the first two inches below this point. Richardson[3] states that in the cadaver all portions of the œsophagus are accessible to the finger, either by means of cervical œsophagotomy or by gastrotomy. He further maintains that the lower three inches of the œsophagus are just within range of gastrotomy. Fagge's[4] experiments on the cadaver do not, however, coincide with the above. In his experience at least two or three inches of the mid-thoracic portion of the œsophagus are inaccessible to the finger. It seems to me that the danger of removing a foreign body impacted in the mid-thoracic œsophagus by cervical œsophagotomy would be almost as great as removal by means of direct œsophagoscopy, if necessary after division of the obstacle, since the risk of laceration of the œsophageal wall during extraction would be considerable with either method. Transmediastinal œsophagotomy has been employed in such cases, but I have no experience of the operation. Fortunately, however, impaction in the mid-thoracic portion of the œsophagus is extremely uncommon, owing to the dilatability of this portion of the tube.

A few special points might be emphasised in connexion with the operation of cervical œsophagotomy. The skin incision should be a long one, in order to allow of free exposure of the œsophagus without unnecessary traction on the important structures in its immediate vicinity. It should be either oblique, taking the line of the anterior border of the sterno-mastoid muscle, or curved, taking the line of cleavage of the skin, as recommended by Kocher, and similar to that which he employs in his operation of thyroidectomy. If possible, the recurrent laryngeal nerve should be isolated and gently drawn downwards and backwards before the œsophageal wall is incised. If the foreign body can now be felt, it may be removed by a vertical incision either immediately over, or better slightly above, this level. If the foreign body, however, be not palpable, it is perhaps better to distend the œsophagus by means of a bougie passed through the mouth before the incision is made. A free incision in the œsophagus will do less damage than much manipulation through a small incision. In

[1] Zeitschrift für Ohrenheilkunde, 1908, vol. i., p. 120.
[2] Operations of Surgery, vol. i., p. 724.
[3] THE LANCET, 1887, vol. ii., p. 707.
[4] Burghard's System of Operative Surgery.

cases of impaction in the upper thoracic portion of the œsophagus it may be necessary to divide the foreign body with cutting forceps before disimpaction can be accomplished without damage to the coats of this tube. It is stated that hæmorrhage from the muscular wall of the œsophagus is often free, but fortunately it caused no trouble in the cases described above. Severe hæmorrhage may, however, occur from accidental division of the inferior thyroid artery, which accompanies the recurrent laryngeal nerve. Efficient drainage should always be established for several days, the drainage-tube reaching down to the œsophageal wall. Suture of the divided pre-tracheal layer of fascia forms an important protection to the underlying line of sutures; sufficient room should, of course, be left for the passage of the drainage-tube.

With regard to the after-treatment, rectal saline should be employed for the first two or three days. In order to allay thirst I found that acidulated tablets, occasionally given, were very effective; they also served to keep the mouth moist and so diminished the risk of "septic parotitis." Steam inhalations, together with some antiseptic, such as menthol or eucalyptus, are also useful in this respect, besides minimising the liability to pulmonary complications to which these patients are prone, due, no doubt to a large extent, to the element of sepsis which is always present, in a greater or less degree, with a wound in the œsophagus. A sitting posture together with the employment of a steam-kettle and tent are also useful precautionary adjuncts. If progress be favourable fluids may be given by the mouth after from 48 to 72 hours. Should there be any leakage through the cervical wound I think it is better not to give the patient milk to drink, since this is very liable to decompose and hinder repair, but chicken broth or even soft solid food—e.g., Brand's jelly—will be found more suitable. In the above cases, although there was a certain amount of leakage at first, this trouble soon ceased when these simple measures were adopted. If possible, the patient should be allowed to get up after a few days, especially if he is very anxious to do so; the good moral and physical effect produced thereby was well illustrated in Case 2.

The chief post-operative complications of cervical œsophagotomy are, for the most part, septic in origin, and may be roughly classified in the following way: Early complications—(*a*) cellulitis, cervical and mediastinal; (*b*) subcutaneous emphysema. Later complications—(*a*) septic pulmonary conditions; (*b*) secondary hæmorrhage. If cellulitis occur, the wound should be freely opened and drained, and appropriate treatment for combating toxæmia should be vigorously enforced. Subcutaneous emphysema is, as a rule, only transitory and disappears in a few days; it rarely gives rise to any discomfort or cause for anxiety. The occurrence of pulmonary complications is best anticipated, and prophylactic treatment, such as that indicated above, should be employed from the first. Secondary hæmorrhage may be a very serious complication and is invariably septic in origin, as illustrated by Case 1, where it occurred on the tenth day after operation, the blood in all probability coming from some vessel in the œsophageal wall or else from the inferior thyroid artery. Jaundice, which was present in Case 1, was almost certainly toxic in origin in spite of the fact that the local condition was quite satisfactory.

In both cases of œsophagotomy detailed in this paper operation was undertaken early, within four and five hours of the accident respectively. Foreign bodies in the œsophagus should be removed as soon after impaction as possible. If other means of extraction fail, œsophagotomy should be promptly undertaken in order to obtain a successful result. In such circumstances the risk of operation is not great, but the prognosis becomes very grave with the advent of cervical or mediastinal cellulitis.

I am greatly indebted to Mr. F. C. Cowtan for his very able drawings of the tooth-plates reproduced in this paper.

Wimpole-street, W.

SOCIETY FOR THE STUDY OF INEBRIETY.—The next meeting of the society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, July 11th, at 4 P.M., when Mrs. W. Bramwell Booth will open a discussion on "The Management of the Inebriate Woman."

MICE IMMUNISED SUBCUTANEOUSLY ARE RESISTANT TO THE IMPLANTATION OF CANCER IN INTERNAL ORGANS.

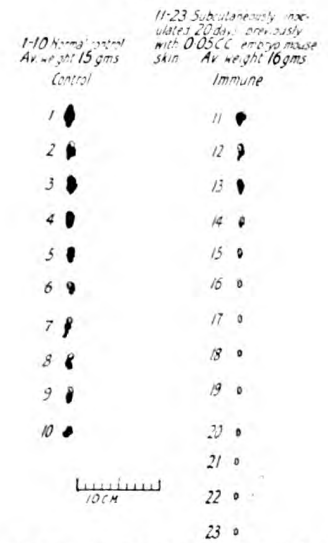
BY W. H. WOGLOM, M.D.,

CROCKER CANCER FUND, COLUMBIA UNIVERSITY, NEW YORK; ASSISTANT TO THE IMPERIAL CANCER RESEARCH FUND, LONDON.

RESISTANCE to the successful inoculation of a tumour has been usually held to be a condition of general and equal distribution throughout the animal's body. A series of experiments carried out last year, however, by Kraus, Ranzi, and Ehrlich [1] led them to doubt the validity of this conception and to conclude that animals rendered resistant by subcutaneous injection of tumour or of normal tissue might not perhaps be so resistant to the inoculation of tumours into their organs as they would be to subcutaneous implantation. The point thus raised by Kraus and his colleagues is of great interest, for should future experiment sustain their suggestion, many of our ideas of immunity would have to undergo revision. In order, therefore, to see whether one had been right in assuming resistance to be a general, rather than a local condition, the following experiment was undertaken.

On March 15th, 1911, a series of mice were inoculated in the left axilla with 0·05 c.c. of an emulsion of embryo skin. Their average weight at that time was 12 grm. On April 4th (20 days later) 13 of them, now of an average weight of 16 grm., and 13 normal controls (of an average weight of 15 grm.) were inoculated in the left kidney with 0·01 c.c. of an emulsion of tumour 63—a mammary adenocarcinoma. Under ether anæsthesia the kidney was approached through an incision in the flank and the inoculation made by means of a syringe fitted with a fine needle. Twenty-five days later the 10 surviving controls and the 13 mice of the experiment were killed and examined and their tumours sketched in outline. In the chart thus made (Fig. 1) the black silhouettes represent tumour, and where

FIG. 1.



Experiment 63 47 J. All mice inoculated in left kidney on April 4th, 1911, with 0·01 c.c.; killed 25 days later, April 29th. The black silhouettes represent the tumours and the kidney-shaped outlines the kidney where this was still recognisable. Note that tumours developed in the kidney of all the normal mice but in only five of the immune mice, and that here they were of much smaller size.

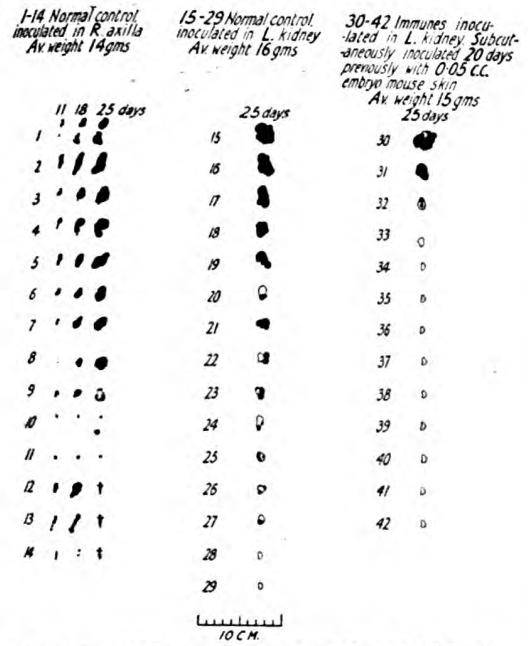
they contain a reniform unshaded area it implies that kidney itself was still recognisable. In many of the ca however, the kidney had been quite destroyed by the gro of the tumour. Where kidney-shaped outlines alone shown (Nos. 16 to 23) it means that no growth visible to naked eye had occurred. It will be seen that while 100

[1] Zeitschrift für Immunitätsforschung, &c., 1910, Orig. vi., 665.

cent. of the normal controls developed tumours, only 46 per cent. of the treated animals did so, and, moreover, that in the latter case the tumours were much smaller.

So much having been gained, it was essential to repeat this preliminary experiment and further to plan a third one, which should concern itself with the relation of subcutaneous to organ immunity within the same animal. The second experiment is reproduced in Fig. 2, and is in all respects a

FIG. 2.

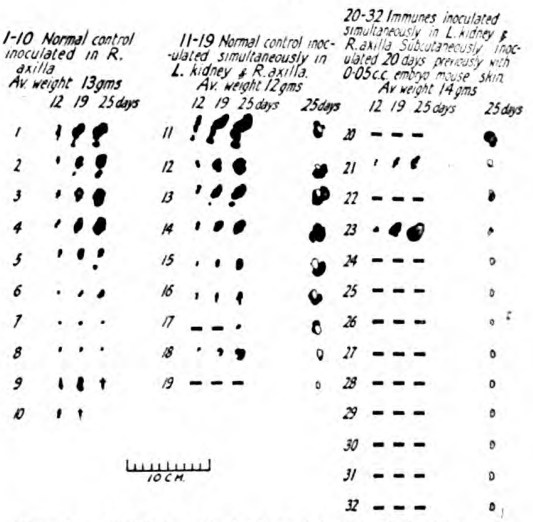


Experiment 63/49 J. All mice inoculated May 26th, 1911, with 0·01 c.c. The black silhouettes represent the tumours and the kidney-shaped outlines the kidney. In the first column (1–14) the progressive growth of the subcutaneous tumours is depicted at three successive chartings up to the twenty-fifth day after inoculation. In the second column (15–29) is depicted the result 25 days after inoculating the same tumour into the kidney of normal mice, and in column 3 (30–42) into the kidney of immune mice. Note the marked resistance in the latter.

replica of the first, except that there is given the result of inoculation of the tumour into the axilla of normal mice. One notices, first, that of these, excluding three mice (Nos. 12, 13, and 14) which died before the third charting of their tumours, 100 per cent. developed growths, and an indication is thus afforded of the proliferative power of the tumour under discussion when implantation is made at the site usually selected. Among the series inoculated in the kidney, transfer of the tumour was successful in 87 per cent., and in passing it is of interest to observe that the size of the tumours growing in this location is not exceeded by those in the axilla. That inoculation may be made successfully into the abdominal organs is a fact which is generally known. The important feature of the experiment falls in the third column and is an entire substantiation of the result pictured in Fig. 1. While 87 per cent. of the normal mice developed tumours of the kidney consequent upon inoculation into that organ, the animals subcutaneously immunised fell far short of this percentage, only 23 per cent. of them presenting growths on the twenty-fifth day.

A third experiment (Fig. 3) completes the chain of evidence, and showing as it does the result of simultaneous inoculation into kidney and axilla in normal and immune animals, permits us to draw certain conclusions regarding the general distribution of the immune state throughout the animal's body. Among nine normal mice (Nos. 11 to 19) inoculated in axilla and kidney there occurred tumours in both locations in 89 per cent., while in the only case in which no tumour was present in the axilla the attempt to inoculate the kidney was also negative. Contrasted with this result is that set forth in the last two columns. In mice subcutaneously immunised, and similarly inoculated, tumours were present in the kidney in only 31 per cent., and, although it is true that in two of the mice (Nos. 20 and 22) which did not develop axillary tumours there had been no bar to the growth of tumours in the kidney, yet it is contended that this was a

FIG. 3.



Experiment 63/49 I. All mice inoculated May 25th, 1911, with 0·01 c.c. The black silhouettes represent the tumours and the kidney-shaped outlines the kidney. Similar experiment to that depicted in Fig. 2, but the mice were tested both by subcutaneous inoculation and by implantation into the kidney, in order to show the parallel distribution of resistance throughout the body brought out by columns 4 and 5 (mice 20–32).

fortuitous circumstance which in no wise invalidates our reading of the result of the experiment.

One feels justified in inferring from the experiments above set forth that the immune state is one of general distribution throughout the organism and not of local occurrence at the site of the immunising inoculation, without wishing, however, to have this conclusion applied to the zonal immunity described by Sticker.[2]

The expense of this investigation was partly borne by the Crocker Cancer Research Fund of the College of Physicians and Surgeons, Columbia University, New York.

THE SOUTHWARK GUARDIANS AND DISSECTION.—At a meeting of the Southwark board of guardians on Thursday, June 29th, the following letter was read from Mr. F. G. Parsons, secretary to the anatomical committee at St. Thomas's Hospital: "It has been reported to me that the Southwark board of guardians has withdrawn its permission for unclaimed bodies to be sent to the London schools of anatomy. This, if true, will cut off one-tenth of the supply and seriously handicap medical education in London. Would you, therefore, kindly tell me whether there is any truth in it, or whether the board has any cause of complaint of the way that bodies entrusted to the various licensed teachers of anatomy are treated? In the event of permission having been withdrawn, will you kindly send me a list of guardians, since their action would be of the very gravest importance to the University of London and should be laid before them in all its bearings." Mr. C. W. Matkin, the vice-chairman of the board, inquired whether only ten boards of guardians in London sent bodies of the friendless to the schools of antomy. The clerk replied that he could not says Mr. F. Haines said he was not ashamed of his action in voting for the abolition of the practice, nor of supplying his name and address. Mr. Matkin: They can obtain our names without coming here. Mr. W. Hills: I do not think we have the slightest objection to our names being seen in print. The clerk was instructed to inform Mr. Parsons of the guardian's decision to discontinue sending bodies of the friendless to any school of anatomy, but not to give the names and addresses of the guardians.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Division of Posterior Spinal Nerve Roots for Pain, Visceral Crises, &c.

A MEETING of this section was held on June 13th, Mr. RICKMAN J. GODLEE, the President, being in the chair.

Mr. E. W. HEY GROVES read a paper on Division of the Posterior Spinal Nerve Roots for Pain, Visceral Crises, &c., which is printed in full in this issue of THE LANCET, p. 79.

Professor FÖRSTER of Breslau discussed the subject in a paper which is published in full on p. 76 of this issue of THE LANCET.

Dr. OTTO MAY showed a case of Little's disease in a small boy who was a premature child, one of twins, who from birth onwards showed well-marked spastic jerks. Medicinal measures having been of no avail, he suggested that the operation of Professor Förster should be performed to enable the boy to walk, and there seemed a prospect now that that operation had been done by Mr. H. S. Clogg that he would be able to walk moderately well, but it was as yet only a short time since the operation. (This case will be found described in THE LANCET of June 3rd, 1911, p. 1489.)

Mr. C. A. BALLANCE desired, before mentioning the two or three cases which he had had bearing on the present discussion, to say what a great personal pleasure it had been to him to listen to the splendid scientific address of Professor Förster, and to express the hope that in the future the Surgical Section of the Royal Society of Medicine would learn the great advantage of inviting our distinguished *confrères* from foreign countries from time to time to join in the discussions and teach English surgeons so much of their work in the way in which Professor Förster had done that day. He was there by request of the President, having had no experience of division of posterior roots for spastic paralysis or gastric crises. The first case in which he divided a posterior root occurred many years ago in a patient of Dr. Risien Russell. The patient was a woman aged about 35, who suffered from herpes in the distribution of the first dorsal root, along the inner border of the forearm, and when he saw her there were certain scars and marks of the previous herpes, which remained after the attack had subsided. But since subsidence of the attack she had suffered in the distribution of the first dorsal root from considerable pain and the area was hyperæsthetic. He divided the first dorsal root on that side, and in doing so he relieved the pain completely. It was at the time that Professor Sherrington was working at the distribution of the posterior roots, and he came many times to examine that patient; and if he had been present at that meeting he could have told members a great deal more about the sensation in the part supplied by the first dorsal root than he (Mr. Ballance) could do. But Professor Sherrington determined that there was a fourth form of sensation, or some new form of sensation which he had never been able to discover before. The exact details of that he would not enter into, but in the periphery of the anæsthetic area the patient was enabled to recognise the burn from a nearly red-hot wire. He did not know whether Professor Sherrington had made any further experimental investigation on the matter, but at that time he was very much interested in it, and he remembered his great anxiety to publish an account of the new form which he had apparently discovered in that first case of division of the first dorsal region. The result of the operation was completely successful. The hyperæsthesia disappeared and all the pain disappeared, and the patient was cured. The case he saw next he did not operate upon, but as he saw it he felt at liberty to mention it. It was the case of a lady whom he saw with Sir David Ferrier and afterwards with him and with another physician and Sir Victor Horsley. She had hyperæsthesia of the sole of the right foot corresponding to the distribution of the posterior root of the first sacral nerve, and she was not able to get about. The hyperæsthesia was not absolutely constant, but whenever it was present in the sole of the foot it was impossible for her to walk about. At that time she was averse to operation, but later on Sir Victor Horsley divided the posterior root of the first sacral nerve of that side, and he heard a year afterwards that she was cured. There was at first some difficulty in getting about because of the anæsthesia of the sole of the foot, but he thought that was overcome and all the distressing pain and the hyperæsthesia in the sole of the foot removed. The third case was that of a young woman of 22. She was under the care of a medical man at Felixstowe. Mr. Ballance saw her last year. When she was a year old she had tuberculosis of the fourth metacarpal bone of the right hand, and there was a considerable scar over that region. There was for many years pain in the scar, and when she had that pain she was unable to do anything which she had been previously accustomed to do. She was neurotic, and since 1898, 10 years before he saw her, she had suffered from epilepsy. The question was whether that painful scar had anything to do with the epilepsy. Convulsions occurred about four times a year, and she had been treated for many years by bromides. She had been seen by a number of physicians, and two years before he saw her Sir Victor Horsley had divided the dorsal branch of the ulnar nerve, which was distributed to the region of the scar over the fourth metacarpal bone. He believed the operation gave some relief at first, but apparently resulted subsequently in an increase of pain. For 18 months before he saw her she had been in great distress on account of the pain in the scar, this pain having spread up the arm in the distribution of the eighth cervical root. He divided this root. There was no difficulty in doing that operation. Dr. Purves Stewart was present at the operation, and with him he took the opportunity of stimulating the anterior roots of the seventh and eighth cervical and also the first and second dorsal. The eighth cervical was the one divided. The triceps acted very powerfully, the pectoralis contracted, there was no flexion of the fingers, but there was extreme hyperpronation of the whole limb. In stimulating the anterior root of the first dorsal there was flexion of all the fingers, ulnar flexion of the wrist, the triceps contracted, and so did the rhomboids. There was no hyperpronation. With stimulation of the seventh cervical anterior root there was extension of the elbow, the pectoralis contracted, and there was hyperpronation. But below the cervical roots there was no hyperpronation and there was no flexion of the fingers until the first dorsal root was stimulated. The second anterior root was also exposed and stimulated, and in stimulating that there was only contraction of the intercostals. The patient was immensely relieved. Six months after the operation she had had no fit and had been able to return to her ordinary occupation. He had not heard of her since and he was sorry that, in view of the present discussion, he had not ascertained her later history. The fourth case was one in which he could not complete the operation. It was the case of a man who came to St. Thomas's Hospital last winter and who was nearly 20 st. in weight. Some years before he had met with an injury which necessitated amputation in the lower third of the thigh. He was a railway man. During the last two years he had suffered from intolerable pain in the stump. All sorts of drugs had been used, the nerve had been injected with alcohol, and the nerve excised as far as it was found in the stump, right up to the sacro-sciatic foramen. Therefore, after seeing him for some time and watching his distress and pain, it occurred to him that the only thing would be to attempt to divide the posterior roots corresponding to that limb. He decided to divide the posterior roots of the third, fourth, and fifth lumbar, and the first and second sacral. The stump was on the right side. In that way he covered the whole sensory distribution of the lower limb, without interfering with the sensory distribution in the genital and anal regions. The patient was anæsthetised, and he got through the eight inches of fat down to the lumbar spine, and managed to get away the laminæ of the second, third, fourth, and fifth lumbar vertebræ, but at that time the patient's condition was so bad that it was necessary to infuse him, and the wound was closed. There was great difficulty in reviving him; indeed, for some time he (Mr. Ballance) thought the patient was dead. Some weeks afterwards the wound was reopened with the intention of dividing the dura and those nerves.

But before he had got down to the dura the man's condition failed again and he could not open the dura. He did not feel that he was justified in doing a brilliant operation at the risk of killing the patient. The man had left the hospital and his doctor reported that he was still in great pain, but still, considering the grave condition in which he was when the other two operations were attempted and that there was considerable work for some hours in getting him back to life, it was not thought advisable to attempt anything further in the operative way.

Dr. PURVES STEWART said that the position of a physician who ventured into a surgeons' meeting was analogous to that of Daniel in the lion's den. But Daniel was cast into the lion's den, whereas he (Dr. Purves Stewart) was at this meeting of his own accord. He supported everything which had been said by Mr. Ballance about the papers which had been listened to. He (Dr. Stewart) had had three cases in which Professor Förster's operation had been carried out. The first and best was one of gastric crises in the person of a man 40 years of age who had intolerable vomiting of some months' duration with intense emaciation. In August, 1909, Mr. William Turner, of Westminster Hospital, divided the thoracic roots from the seventh to the tenth inclusive on both sides, and the result was the production of a band of anæsthesia such as Mr. Groves showed on the screen, from the xiphisternum to the umbilicus. It completely stopped the man's gastric crises; he rapidly put on weight and became a normal member of society. But in consequence of his occupation he developed another trouble—namely, alcoholic poisoning. The second case was one with tabetic lightning pains in both legs. The case came to the West End Hospital for Nerve Diseases. Mr. Wilfred Trotter divided the third lumbar roots and the result was practically *nil*. Some anæsthesia was produced in the area of the roots, but the pain continued. The third was a case of spastic paraplegia in a man who had syphilitic softening of his cord many years ago, and spasticity in his legs, without sensory changes, but with marked bladder trouble. The arms were normal. Mr. Trotter divided the first, third, and fifth lumbar roots on one side, and the second and fourth lumbar roots and first sacral on the other. The result was that the man, instead of walking with one toe just in front of the other, could now take steps three times as long as before, the spasticity was diminished, and he was so pleased with the result that he wanted to have further roots divided so that he might be further improved. The operation of Professor Förster was a very brilliant one, but, like all other operations, it was only suitable in selected cases, as Professor Förster himself pointed out. The cases *par excellence* where the operation was indicated were those of gastric crises. As Professor Förster had shown in numerous papers, the gastric crisis was a nerve storm of the reflex arc, or of several reflex arcs, and if such arcs were cut the storm ceased, because there was no longer a path in which it could travel. With regard to tabetic pains matters were different. Tabes was not simply a disease of the roots, but of the continuation of the roots in the spinal cord. Division of those roots for the pain in tabes could not be expected to cure the disease; the central parts of the roots still remained and still could cause pain. With regard to the treatment of the ataxia, to employ Professor Förster's operation for ataxia was unjustifiable, because it would tend to increase the ataxia. With regard to cases of spastic paralysis one must be very cautious not to employ Professor Förster's operation indiscriminately in all cases of spastic paraplegia, because in every case there were two elements, spasticity and paraplegia, and of those two elements Professor Förster's operation could only relieve the spasticity. If it was found on anæsthetising the cord with stovaine, as Professor Förster suggested, that there was still some voluntary power, it was worth while dividing the roots, and there would be that amount of voluntary power which the pyramidal tracts were capable of. But if a patient was idiotic or so severely paralysed that his pyramidal tracts were almost completely degenerated, it was not worth while removing his spasticity. That and athetosis were contra-indications of it, because the latter meant that the brain was degenerated, and no amount of posterior division would remove it. And, as Professor Förster pointed out, disseminated sclerosis or other central disease was a contra-indication for the operation.

Mr. D. M. AITKEN, referring to the great importance of after-treatment in cases of spastic paraplegia, said he had been watching these cases for the last 30 years, since he was house surgeon to Mr. Robert Jones of Liverpool, who treated those cases on orthopædic lines. He asked whether Professor Förster would draw the line between cases suitable for pure orthopædic treatment and cases in which he would at once go in for section of the roots? He thanked him for the splendid demonstration of results. With regard to reflex spasm, it was cases of that sort which Mr. Jones and he treated orthopædically, but in which Professor Förster divided the roots of the nerves. Were they the primary source of that spasm he would like to know with certainty. Was he right in assuming that that spasm came from the muscles themselves? And if that was so, why should not that be overcome by division and full stretching of the muscles? He was asking those questions entirely for information, because the cases he had seen numbered now about 50, and in some of them there was good recovery in the lower limbs. In the marvellous fourth case of Professor Förster the photograph showed that abduction of the thumb was very good. Spitza of Gratz had done much in transplantation of nerves in connexion with these cases, and as far as he could tell the great difficulty had been with the thumb. In the same way, the orthopædic difficulty had been to overcome the spasm of the thumb. He would also like to ask how soon the children operated upon could be got to use their thumbs. The hands were the most difficult part to treat.

Dr. C. M. HINDS HOWELL said he had at present under care a man who was a tabetic, with very severe gastric crises. He had been treated with every conceivable sort of medical method for these, and, finally, last summer he decided to have tried the operation of division of the posterior roots. Pain was the predominant characteristic of his attacks; the vomiting seemed to be secondary. The patient got some relief by making himself sick. The maximum point of pain was just above the umbilicus. The fibres which were divided by Mr. Warren Low at the Great Northern Hospital were the eighth, ninth, and tenth posterior divisions of both sides. The man recovered from the operation, but the gastric crises were not permanently benefited, though they were better for six weeks. He was having the crises at the rate of three or four a week. Possibly sufficient roots had not been divided, probably the seventh and eleventh should have been cut. But it did not follow that the gastric crises were simply due to irritation of the root outside the spinal cord. As Dr. Purves Stewart said, there was degeneration going on inside the cord, and he did not think one could separate off gastric crises from the lightning pains. The operation was not invariably successful for the lightning pains, and one could not expect it to be always so in gastric crises, and he did not think one should indiscriminately start cutting the posterior roots in tabes or gastric crises unless one had considered the matter very carefully indeed.

The PRESIDENT again thanked Professor Förster for coming so far to read his paper. He asked whether Professor Förster would advise as a routine matter division of the posterior roots in Pott's disease where there is much spasm. That was an operation which one frequently had to perform where spasm had been very marked, and his experience had been that the spasm had always subsided in almost all his cases. But in the last case but one which came under his care he could not say the spasm altogether disappeared when the patient left the hospital. One did not feel very keen about opening the theca when one was working in tuberculous abscess.

Professor FÖRSTER, in reply, said he advocated division of the posterior roots only in cases of extreme spasticity, but in ten cases operated upon by Küttner six were treated for a long time by ordinary orthopædic measures, but without success. It was difficult to decide immediately if a case was suitable for division of the posterior roots, and it was good to try orthopædic treatment first in all cases. Spasm of the adductors had been removed immediately by division of the posterior roots. Dr. Spitza of Gratz had done much work in implantation of the median nerve into the radial, and it was a very good idea, but the spasticity did not disappear. In Pott's disease division of the posterior roots should only be tried when one could be sure the disease was not going on more. If there was no certainty that the tuberculosis of the vertebral column was cured the posterior roots must not be divided. The only case

reported was one in which he and his colleagues tried first a laminectomy of the cervical region, but there was no good effect from it. Later division of the posterior nerve roots in the lumbar region was tried and the spasticity disappeared completely.

EDINBURGH OBSTETRICAL SOCIETY.

Chylous Mesenteric Cyst simulating Pelvic Tumour.—Repeated Cæsarean Section for Contracted Pelvis.

A MEETING of this society was held on June 14th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Professor J. A. C. KYNOCH (Dundee) read notes on a case of Chylous Mesenteric Cyst, simulating a Pelvic Tumour. He said that the most important physical signs of these cysts were: the most prominent part of the tumour was near the umbilicus; they were extremely mobile, so that the cyst might be readily pushed from one side of the abdomen to the other and to a certain extent up and down; and there was a note of resonance on percussion all round the tumour, with very frequently a resonant band crossing the swelling. The most outstanding symptoms were pain over the tumour, intestinal disturbances, attacks of vomiting, with persistent diarrhœa, and general wasting, due in all probability to interference with the lacteals of the mesentery. The patient was aged 37 years and had noticed a swelling increasing in size for three years. She had had three children, the labours being uncomplicated. In the hypogastric region a well-defined, tense tumour was palpated, nodular on the surface, and extending from the left iliac fossa to about an inch to the right side of the umbilicus; its mobility was very marked. There was a resonant percussion note round two-thirds of the tumour. Per vaginam, a cystic swelling of the size of a lemon was felt in the right fornix; it seemed to be intimately connected with the uterus. At the operation an ordinary multilocular cyst of the right ovary was found and removed. The uterus and left ovary were normal. The abdominal tumour had the appearance of a parasitic fibroid, but further investigation showed it to be situated between the layers of the mesentery of the lower part of the ileum. A small incision showed its contents to have a milky appearance, which on later investigation proved to have all the characters of chyle. The cyst was enucleated, the divided edges of the peritoneum being brought together by sutures, and a glass drainage-tube was inserted into the seat of the wound. The patient made a satisfactory recovery. — Dr. J. HAIG FERGUSON, Dr. J. W. BALLANTYNE, and the PRESIDENT made remarks on the subject.

Dr. JOHN MCGIBBON read a paper on Repeated Cæsarean Section for Contracted Pelvis, with notes of a case successfully performed for the third time on the same patient. He pointed out that the subject of repeated section had been discussed at various obstetrical societies during the past year. Routh, in a valuable and elaborate paper read before an International Congress of Obstetrics held at St. Petersburg last September, pointed out that the teaching of Mauriceau of Paris must have greatly influenced British obstetricians, and that his condemnation of Cæsarean section in 1752 had apparently the effect of holding British operators in check, as until 1821 only a few Cæsarean sections were performed, and all with one exception ended fatally. The conservative operation, with a mortality of about 90 per cent., still struggled on until 1876, when Porro introduced his method of supravaginal hysterectomy with extra-peritoneal treatment of the stump, which seemed as if it were going to displace the conservative Cæsarean section. In 1888 some successful conservative sections were reported and this operation gradually gained favour, the mortality steadily diminishing. Thus in 1890 the mortality had fallen to 38 per cent. and ten years later to 20 per cent. Now the mortality, if section was performed before labour, was 2·9 per cent. Dr. McGibbon's patient had her first labour terminated by craniotomy and her next three pregnancies by Cæsarean section. She had a generally contracted pelvis with a true conjugate of from 3 to 3¼ inches. The third operation revealed only a fine linear depression as the trace of the previous scar. There was no thinning of the uterine wall in the scar region and, contrary to the experience of many, there were no adhesions. When compared with premature labour as the operation of election in such a case, Cæsarean section had distinct advantages. The fœtal mortality of induced labour in a pelvis of from 3 to 3¼ inches was stated by some authorities to be not less than 10 per cent. In a series of cases induced in successive pregnancies by Dr. McGibbon the fœtal mortality had been practically *nil*, provided the labour ended spontaneously. When, however, after the induction, forceps were required the mortality was nearly 50 per cent. If at the thirty-fourth week the head could not be pushed through the brim, the chances of a spontaneous delivery with survival of the child after an induction became most uncertain, and then Cæsarean section became the operation of choice. For the performance of the classical Cæsarean section various incisions were proposed and practised, but the transverse fundal and the median longitudinal on the anterior wall were the only two much employed in this country. In recent years attempts by Frank, Sellhein, and others to perform an extra-peritoneal Cæsarean section had been carried out, the original aim being to empty the uterus in infected cases without contaminating the peritoneal cavity. Such methods had been disappointing, as they had been accompanied with various injuries to the peritoneum and bladder, and had had a morbidity of 30 per cent. Sellhein suggested the production of a utero-abdominal fistula in infected cases. The difficulty in the past had been with the doubtfully infective cases, but there seemed to be hope from recent bacteriological investigation that intra-uterine swabbings might identify the presence of pathogenic organisms and so indicate the course to be followed. Craniotomy was indicated in cases believed to be infected, as Cæsarean section became risky and craniotomy showed a smaller mortality. The question of adhesions between the uterus and abdominal wall had always been a source of anxiety to the operator. These would take place by accident in some cases. Wallace of Liverpool intentionally fixed the uterus to the abdominal wall with the object of being able to perform a future section without entering the peritoneal cavity. This procedure had been condemned by some as predisposing to rupture. The relation of repeated section to rupture was important. Mason and Williams, from experiments on animals, had concluded that a carefully united uterine scar would stand any strain which the uterine muscle was capable of enduring, and they maintained that rupture was dependent upon imperfect consolidation. It was an established fact that the mortality of repeated Cæsarean section was rather less than of the primary operation. It was not the duty of the surgeon to advocate sterilisation; he should lay the possible risks before every woman who came to him desiring a living child by repeated Cæsarean section and be ready to perform it on a third, fourth, or further occasions if requested by the patient to do so.—Dr. D. BERRY HART, Dr. HAIG FERGUSON, Dr. BALLANTYNE. Dr. W. FORDYCE, Dr. J. LAMOND LACKIE, Professor KYNOCH, and the PRESIDENT discussed the paper, and Dr. MCGIBBON replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on June 5th, Mr. T. Gunton Alderton being in the chair.—Mr. Leonard Bidwell read a paper on the Immediate and Ultimate Results after Gastro-enterostomy for Gastric and Duodenal Ulcer, basing the paper on 180 cases on which he had operated. The immediate mortality after the operation was about 7 per cent., but in most of the fatal cases the operation had been performed for hæmorrhage, the mortality in uncomplicated cases being practically nothing. Of the cases which recovered and could be traced, about 80 per cent. were completely cured, 10 per cent. were relieved, and 10 per cent. derived little benefit. Attention was drawn to the necessity for the occlusion of the pylorus in cases of duodenal and pyloric ulcer, since the operation of gastro-enterostomy alone was likely to be followed by a recurrence of the ulcer. It was also pointed out that gastro-enterostomy alone was useless in the case of an ulcer situated at a distance from the pylorus. In such cases it was advised that the ulcer should be excised at the same time that the gastro-enterostomy was performed. In conclusion, operation was recommended in every case of duodenal ulcer and in cases of gastric ulcer which had resisted medical treatment.—Dr. F. G. Crookshank considered that cases of gastric ulcer, if treated properly by drugs, &c., would not show a mortality anything like 10 per cent. The mistake in failing to diagnose

them properly accounted for many which ultimately required surgical treatment. With regard to duodenal ulcers he thought most cases with established diagnosis should be operated on early.—Mr. Walter E. Fry, Mr. R. Bevan, Mr. W. P. Mallam, and Mr. T. R. Atkinson joined in the discussion, and Mr. Bidwell replied.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on June 14th at the Royal Army Medical College, Millbank, Colonel Sir David Bruce, A.M.S., being in the chair.—Major C. F. Wanhill, R.A.M.C., read a paper on the Supply of Water in the Field. After pointing out the disadvantages of very large units, such as the brigade sterilising unit, he came to the conclusion that the best unit was a half battalion water-cart. The desiderata for such a cart were that it should be mobile, simple and rapid in action, and should not contain any fragile parts which if broken would render the apparatus useless. Taking these points into consideration, candle filters, ultra-violet ray apparatus, heat exchange sterilisers, and chemical methods of sterilising, were all unsuitable for the provision of large quantities of pure water in the field, though chemical methods had their uses in the purifying of small quantities of water for detached individuals. Experiments at the Royal Army Medical College and at Aldershot had resulted in the devising of an apparatus which depended for its action on the precipitation of the mud in the water by means of alum; the water so treated was passed through flannelette and the mud became deposited on the cloth, forming a layer which acted in much the same way as the zooglea layer on a sand filter. The clarified water which passed through had from 60 to 80 per cent. of the original germs removed, and if it was necessary to remove all the germs, as might happen in the presence of specific contamination, the clarified water could be further passed through porous candles. The candles which were used would only remove 30 per cent. of the germs in untreated water and they became blocked almost at once; but with clarified water the whole of the remaining germs were removed and the output, at the rate of 120 gallons per hour, was constant. Major Wanhill then gave a demonstration of the new water-cart.—Major W. S. Harrison, R.A.M.C., Colonel Ryan, Australian Army Medical Corps, and Colonel Sir David Bruce took part in the discussion.

Reviews and Notices of Books.

Modern Treatment: The Management of Disease with Medicinal and Non-Medicinal Remedies. In Contributions by American and Foreign Authorities. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica, Jefferson Medical College, Philadelphia; Physician to the Jefferson College Hospital. Assisted by H. R. M. LANDIS, M.D., Director of the Clinical Department of the Phipps Institute (University of Pennsylvania). In two volumes. London: Henry Kimpton. 1911. Vol. I., pp. 900; Vol. II., pp. 930. Price £3 net.

THIS work contains an immense amount of information and deals with all forms of therapeutics. At one time the means at the disposal of the physician and surgeon consisted mainly in drugs, in climate, in hydrotherapy, and electrotherapy; but within the last 15 or 20 years the wide and fruitful fields of treatment covered by serum-therapy and the various vaccines have been developed, with a far greater approach to specific treatment than has ever been previously achieved. Further, during the time that these advances have been made the pharmacologist and the chemist have increased the materia medica, with the result that remedies are more thoroughly understood, new ones of great value have been evolved, and most of them can now be obtained in a form in which they can readily be made use of. The appearance of a work which places in the hands of the physician a competent summary of many of these advances is, therefore, timely, and the editors have succeeded in placing before the profession a most useful work of reference.

In an interesting preface Dr. Hare reviews some of the more prominent points connected with therapeutics in general. He draws attention to the relations that exist between the pharmacologist and the physician. If a given dose of a given remedy were always suitable for a given ailment there would be little need for the physician except as a diagnostician. It is the never-ceasing changes in all living persons and the different effects of disease in different individuals that confer value on the bedside experience of the medical man. The pharmacologist may lay down the fundamental processes, but the clinician must make the distinctions in their use which develop the desired results. The opinion expressed by Dr. Hare of the attitude which should be adopted by the competent medical man of to-day will be cordially and generally accepted. The practitioner must be a clinical investigator, who welcomes every gain in knowledge as an additional aid in his efforts to do good. He must ever be controlled in his practice by the fact that he is treating a patient, not a disease, a patient whose powers of dealing with a malady are marvellous, with an organism that is to be directed, not driven or forced, into the right path.

Dr. Hare has been wise in the selection of the contributors for the various articles. Thirty physicians have assisted in bringing this work into the form of a system of modern treatment. It would, perhaps, be invidious to pick out for comment any one or more of the contributions, but without detracting in any way from the others we would draw the attention of our readers to the following: The Untoward Effects of Drugs, by Dr. R. D. Rudolf (Toronto); Serum-Therapy, by Dr. W. H. Park (New York); Tuberculin as a Therapeutic and Diagnostic Agent, by Dr. F. M. Pottenger (Monrovia, Cal.); and Tuberculosis, by Dr. H R. M. Landis (Philadelphia).

A full index is provided, which renders reference to any particular subject easy and rapid.

The Mechanism of Life. By Dr. STÉPHANE LEDUC, Professeur à l'École de Médecine de Nantes. Translated by W. DEANE BUTCHER. London: Rebman, Limited. 1911. Pp. 172. Price 6*s.* net.

Professor Leduc's physico-chemical theory of life and spontaneous generation has excited not a little opposition on the Continent. We question if in its English garb it will be hailed with enthusiasm either by biologists or physicists. It appears that in 1907 the Académie des Sciences did not include in its *Comptes Rendus* the author's work on Osmosis. We have travelled far from the days of John Hunter's "Vital Principle," and now for the "principle of life" we have "The Mechanism of Life," which is an attempt by a physicist to explain so-called living phenomena on physical lines. We are told that the step between a stalagmite and a polyp is less than that between a polyp and a man; that "what constitutes a living being is its form"; and that biology is but a branch of the physico-chemistry of liquids. As the basis of the author's doctrine is physical he gives an account of solutions, electrolytic solutions, colloids, diffusion and osmosis, periodicity, cohesion and crystallisation, karyokinesis, and energetics. This, with the introductory matter, occupies more than one-half of the text, which is illustrated by a number of figures showing liquid diffusion and various patterns produced by adding one chemical substance to another, whereby, as is well known, various forms of "artificial cells" and membranes can readily be produced. He goes even so far as to speak of a fringe of cilia obtained by sowing coloured drops of concentrated salt solution in a weaker salt solution.

The last 70 pages are devoted to what the author calls "synthetic biology." In this chapter, while the author

mentions Montgomery's paper (1867) on the Formation of So-called Cells, we failed to find a reference to Rainey's well-known work on a similar subject (1858), or to that of W. Miller Ord. We then come to what is called "osmotic growth, a study in morphogenesis," a chapter which is illustrated by a large number of figures showing the outward similarity of many of these so-called growths or formations to various familiar botanical and zoological forms. Stem-like forms are produced by sowing a mixture of $CaCl_2$ and $MnCl_2$ in a solution of alkaline carbonate, phosphate, and silicate, terminal organs, like catkins, developing in a solution of ammonium chloride; we have also osmotic madrepores and mushrooms, and so on. The author hopes to find in the play of these physico-chemical forces the road which will lead some day to the discovery of the origin and the evolution of life upon the earth.

Diseases of the Spinal Cord. By R. T. WILLIAMSON, M.D. Lond., F.R.C.P. Lond., Assistant Physician, Royal Infirmary, and Lecturer in Medicine, Victoria University, Manchester. Oxford Medical Publications. Second Impression. With 183 illustrations and 7 plates. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 432. Price 15*s.* net.

THE second edition of this excellent text-book has been enlarged by the inclusion, in an appendix, of paragraphs relating to epidemic poliomyelitis, the operative treatment of gastric crises in tabes dorsalis, of spinal serous meningitis and of spastic paraplegia, and the X ray treatment of syringomyelia. Dr. Williamson still adheres to the description of "ataxic paraplegia" as a separate entity, although the microphotographs of the condition which he furnishes are suggestive of subacute combined degeneration of the cord. He maintains, further, that progressive muscular atrophy and amyotrophic lateral sclerosis are pathologically distinguishable, but the evidence cannot be said to be entirely convincing. Some of the diagrams, for instance Fig. 22, are not, perhaps, quite so clear as the beginner in neurology might desire. The statement that "it has been frequently observed that syringomyelia has followed injury to the back" surely requires some substantiation. The rôle of trauma in syringomyelia is most debateable; even the cases reported in Guillain's well-known "Thèse de Paris" of some ten years ago are open to question, and they were cases observed and examined with the greatest care and insight. Criticisms such as the above, however, are of minor significance in view of the general excellence and comprehensiveness of the volume, which can be recommended confidently to student and practitioner alike.

Traité d'Histologie. Par A. PRENANT, Professeur à la Faculté de Médecine de Paris; P. BOUIN, Professeur à la Faculté de Médecine de Nancy; et L. MAILLARD, Professeur Agrégé de la Faculté de Médecine de Paris. Tome II., Histologie et Anatomie Microscopique. With 572 figures in the text, of which 31 are printed in colours. Paris: Masson et Cie. 1911. Pp. xl. + 1200. Price 50 fr.

THE authors are to be congratulated on the appearance of this, the second, volume of the French standard treatise on histology. The first volume has already been published, and it deals exhaustively with general and special cytology; the present volume completes the work and treats of histology and microscopical anatomy. M. Prenant and M. Bouin are the authors of this portion of the work, which fully maintains the high standard reached by its forerunner.

The work is divided into ten books, comprising some 60 chapters, and when it is stated that the entire volume contains 1240 pages and 572 illustrations, some idea may be gained of the thoroughness with which the subject is treated. Indeed, the undue bulk of the volume is the only criticism we would level against this excellent treatise, for a paper-covered octavo volume over three inches thick is not at all convenient to handle. The illustrations are uniformly good, nearly all of them are original, and many are reproduced from excellent micro-photographs. The text is clear; the treatment is exhaustive and thoroughly up to date.

The schools of France are to be congratulated on the completion of this monumental treatise upon the microscopical structure of the body. In the Prenant-Bouin-Maillard Histology and the uniform Poirier-Charpy-Nicolas Anatomy France possesses the best modern treatise upon gross and microscopic anatomy published in any language.

Text-book of Nervous Diseases, for Physicians and Students. By Professor H. OPPENHEIM of Berlin. Fifth enlarged and improved edition, with 432 illustrations in the text and 8 plates. Authorised Translation by the late ALEXANDER BRUCE, M.D. Edin., F.R.C.P. Edin., LL.D., Physician to the Royal Infirmary, Edinburgh. In two volumes. Edinburgh: Otto Schulze and Co. 1911. Pp. 1424.

THE desire of the translator of Professor Oppenheim's well-known text-book has been to render a work that enjoys so high a reputation more accessible to English and American readers. Every endeavour has been made to reproduce the meaning of the German text exactly and clearly, and in conformity with Professor Oppenheim's wish the volumes have not been in any way edited. But those who are familiar with previous editions of the text-book will note with pleasure that the value of the present edition has been considerably enhanced by the inclusion of numerous bibliographical references, which have been chosen with noteworthy judgment. The most important and valuable articles on each subject is quoted, as well as the monographs and *résumés*, from which the reader can conveniently trace his way back to the older literature. The subject-matter of the book has been enriched by taking into consideration all recent advances in the study of nervous diseases and their treatment. The illustrations have been augmented and X ray photographs have been incorporated. In these two handsome volumes, then, the practitioner and the student will find their respective neurological needs adequately catered for, and the specialist himself may consult them with advantage, inasmuch as they contain the results of the lengthy clinical and pathological experience of one who has devoted his life to the elucidation of nervous disease. The responsible task of translating has been accomplished with conspicuous success by Dr. Bruce, whose recent death is greatly to be deplored. Presented in this guise to English readers, Oppenheim's text-book should increase its already wide popularity, while its introduction to a larger circle of readers marks another step in the steady advance which neurology is making.

Die Zeugung beim Menschen. (*Generation in Man.*) By Dr. HERMANN ROHLEDER. With an appendix on Artificial Impregnation in Man. Leipzig: Georg Thieme. 1911. Pp. 290–777. Price M. 7.

IN this book the author considers the question of generation in the human subject primarily, and more especially the possibility of artificial impregnation in the human female and the many moral and legal questions concerned therewith. After a section devoted to a consideration of the process of generation in general and its laws, the second section of the book is devoted to the many questions associated with its physiology. This includes an account of the nature and development of the semen, the physiology of erection of the penis and ejaculation, the functions of the prostate and of the glands of Cowper. Menstruation and ovulation are then

discussed in detail, and finally insemination and fertilisation. Such important questions as fertility and sterility are also considered, and the problems of super-fecundation, super-fœtation, heredity, and the determination of sex. The author next takes up the pathology of generation and the many etiological factors concerned therewith.

The appendix deals very fully with the question of artificial impregnation in the human subject. After some pages devoted to a consideration of sterility Dr. Rohleder passes on to discuss the indications and contra-indications of this procedure. The technique of the operation and the methods of carrying it out are all described. Its results are also considered and its relation to religion and the morals, both of the individuals concerned and of the medical man who practises it. The author maintains that a medical man is right in employing this means of correcting sterility, that it is a helpful therapeutic measure, and that he is, indeed, bound in any given case, if need be, to try this method when others fail. It is obvious, therefore, that Dr. Rohleder takes up a very strong position on this point, and he has himself carried out the procedure in some six cases. In four of these cases there was no result, in one case a possible miscarriage after a period of amenorrhœa of five and a half weeks' duration, and in the last case a successful result, the woman giving birth to a healthy child at full term. The question of artificial impregnation hardly deserves the amount of attention the author has given it, but for a full discussion of the whole subject from all points of view anyone interested in the matter may refer to this very complete work. In conclusion, the author considers that the method is of importance, not only from the point of view of the individual, but also from that of the nation, since in it he sees a possible remedy for the 10 per cent. of sterile marriages, which he regards as a national calamity.

LIBRARY TABLE.

Care of the Patient: A Book for Nurses. By ALFRED T. HAWES, A.M., M.D. With 6 illustrations. Philadelphia: P. Blakiston's Son and Co. 1911. Pp. 173. Price $1.00 net. —This little work is primarily a text-book of medical, surgical, and maternity nursing for American nurses, and is in many respects a useful compilation. The success or failure of medical treatment to a great extent often depends on the nurse. A physician may outline medical treatment and a surgeon may operate successfully, but the patient's recovery depends frequently on the skilful performance of the details of nursing. Where a surgeon has to leave many details before and after operation to a nurse, an unclean instrument, carelessness in preparing surgical dressings, the omission of any one of the numberless details in preparing a patient for an operation, may cause disaster and turn the scale against the patient's recovery. For this reason any thoughtful addition to the scientific aspects of nursing from the pen of a medical man is welcome. Many of the procedures are described rather minutely, but in skilled nursing it must be admitted that no detail is so trivial that it can be neglected. The text is methodical in its arrangement, the type is good, and there is a satisfactory index.

Outlines of Medical Jurisprudence and Treatment of Poisoning. By RAMES CHANDRA RAY. Calcutta: Published by the Author from the Hare Pharmacy. 1910. Pp. 244. Price 2 rupees.—This volume is intended mainly for the use of students and practitioners in India. The author shows considerable ability and a thorough knowledge of the subject in the way in which he has compressed so much information into a comparatively small space. He remarks that "we are a fast-living generation, living in the days of tabloids, and having just enough time to be contented merely with bird's-eye views of subjects." He, therefore, suggests that this book may be considered a tabloid of jurisprudence, suitable for a medical jurist in an out-of-the-way "mafossal" station where he has no more pretentious books at hand. The subject matter has been admirably arranged, and the free use of comparative tables greatly aids in the explanation of the numerous problems that may arise in medico-legal work. We believe that the book will be found of great value by those for whom it is intended. Students in this country also would find it of use in refreshing their memories after studying the larger text-books on the subject.

Sight Testing Made Easy. By W. WRIGHT HARDWICKE, M.D. St. And., M.R.C.P. Edin., L.R.C.S. Edin. London: J. and A. Churchill. 1910. Pp. 76. Price 2*s.* 6*d.* net.—This little book may prove useful to the general practitioner as a stimulant to memory, provided he has had a good grounding in refraction. It may also prove a useful help as an introduction to the study of refraction by the student. The present edition has added to the subjective sight testing to which the former edition was confined some notes on retinoscopy, the objective form of sight testing.

Health Hints and Health Talks. By E. R. PRITCHARD, Secretary of the Chicago Department of Health. Chicago: The Reilly and Britton Co. 1911. Pp. 153. Price 50 cents. —This little book contains much useful health knowledge for the laity, written in a breezy and interesting style, as befitted material that was originally compiled in accordance with the scheme of general hygienic education so well carried on by the Chicago Department of Health. These hints and talks appeared in the *Chicago Tribune* and other newspapers, and are now collected into an attractive little volume for discursive reading by a wider circle of readers. They contain essentially practical advice to be intelligently carried out, rather than platitudes to be read and forgotten; and they embrace so large a field that there are few, whether laymen or general practitioners who have to advise laymen, who will not benefit by the perusal of them.

The Pharmacopœia of the Queen's Hospital for Children (formerly the North-Eastern Hospital for Children). Compiled by a Committee of the Medical Staff. Fifth edition. London: H. K. Lewis. 1911. Pp. 73. Price 2*s.* 6*d.* net. — All practitioners who have much to do with children's ailments, and that includes most of those medical men in wide general practice, will find many useful suggestions in this little pocket formulary. In addition to the approved formulæ used at the hospital, it contains much useful information on the care and management of children, both in health and in those forms of disease to which they are especially liable, as well as the customary tables.

The Girls' School Year Book (Public Schools) 1911. London: The Year Book Press. Pp. 606. Price 2*s.* 6*d.*— This is the official book of reference of the Association of Head Mistresses, and contains concise accounts of many matters connected with the education of girls which will be useful both to parents and teachers. The book is divided into two parts, the first of which contains a list of the leading girls' public schools—i.e., schools having a governing body, as distinct from private institutions, with information as to staffs, examinations, scholarships, fees, and so forth. The second part is devoted to a series of articles on various subjects, including professions and occupations suitable for girls, with the qualifications necessary and the cost of training.

Across the Bridges. By ALEXANDER PATERSON. London: Edward Arnold. 1911. Pp. 273. Price 6*s.*—The more exact our knowledge of the home life of the poor and of influences for evil which surround the growth of the child,

the more easy will it be to apply practical remedial measures to the very pressing problems of social reform, though it must not be forgotten that all satisfactory solutions of social questions must ultimately depend upon a general quickening of the responsibilities, not of any one class, but of the whole community. Mr. Alexander Paterson, who has spent many years among the poor in South London, has given us in "Across the Bridges" a vivid description of life among the poor in the squalid districts on the south side of the Thames, from birth to marriage, death often taking place in the workhouse, the hospital, or the street. Particularly valuable is the chapter on school influences, in which the author rightly points out that the primary object of a school is not to convey knowledge or teach a trade, but to make boys into men, a very difficult task when it is remembered that among the class described the boy "will look to become a man at the age of 14." Moreover, in the elementary schools the teachers are only teachers and never, save in a few rare instances, masters, as that term is understood in our public schools, where the master can mould and develop a boy's life. Mr. Paterson recognises the great utility of medical inspection in the schools and believes that the most beneficial of school influences lie in the direction of health. For "Across the Bridges" there is a great waste of life which, given other environment, would develop into a valuable asset to the State. The Bishop of Southwark, who writes an introduction to the book, states an important truth when he says: "There is no lack of sympathy in English hearts; there is a great lack of mutual knowledge in different classes. The increase of such knowledge is among the very first of our national needs." The sketches which Mr. Paterson has drawn of a certain phase of London life should do much to supply that knowledge within their indicated limits.

Progressive Medicine: A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, &c. Assisted by LEIGHTON F. APPLEMAN, M.D. Vol. IV., December, 1910. London: Rebman, Limited. Pp. 360. Price annually £2 net, or 12*s.* per volume.—The volume before us deals with diseases of the digestive tract, with diseases of the kidneys, with genito-urinary diseases, with the surgery of the extremities, and with recent advances in therapeutics. The article on the digestive system is by Dr. R. S. Lavenson, and contains an interesting review of papers dealing with dilatation of the œsophagus, with gastric ulcer, with the diagnosis of carcinoma of the stomach, and with the form of dyspepsia associated with chronic disease of the appendix. It is the opinion of the author that Cammidge's reaction is not of diagnostic value, depending largely on the food consumed, and the introduction of magnesium salicylate as a remedy for flatulence. The kidneys are dealt with by Sir John Rose Bradford, who discusses recent work on vascular hypertension, on albuminuria as a sequel of nephritis, on infection of the urinary passages by bacillus coli, and the formation of calculi. In the chapter on the surgery of the extremities, written by Dr. Joseph C. Bloodgood, the value of tincture of iodine as a first application to wounds is recorded, and much work dealing with military surgery is analysed. The almost invariable occurrence of infective processes after gunshot wounds is emphasised, the dangerous organisms being those of tetanus and of malignant œdema. Successful transplantation of joints is recorded, and the method of interposition of tissues after resection to maintain the mobility of articulations. Dr. W. T. Belfield, who writes on genito-urinary surgery, calls attention to the recent view that hydronephrosis may ensue after an acute total blockage of the ureter, and to the use of vaccines in urinary work. He also analyses papers dealing with the influence of the secretions of the ductless glands, especially of the adrenal bodies, on the sexual organs. Recent advances in therapeutics are discussed by Dr. H. R. M. Landis. We may mention among the subjects alluded to the use of acetone in inoperable cancer and the employment of adrenalin in cases of plague. This digest has now established itself as a most important summary of medical and surgical progress, and might well find its way to the bookshelves of all who wish to keep abreast with the advance of science. It is well printed and got up, and contains many illustrations, some being in colours.

Talks About Ourselves: Simple Lessons in Hygiene and Physiology. By KATHLEEN FALMOUTH. With a frontispiece by T. C. GOTCH. London: George Routledge and Sons, Limited; New York: E. P. Dutton and Co. 1911. Pp. 350. Price 1*s.* 6*d.* net.—Lady Falmouth is to be congratulated upon a thoroughly sensible little work. The "talks" are intended to assist parents and teachers as well as to instruct boys and girls, and they make up a book which is a happy blend of thoroughness and simplicity. A really intelligent child, reading the book carefully, would obtain unaided a rough grasp of physiology, while the parent and teacher will find in the different chapters material out of which valuable lessons to pupils can be constructed, and apt replies derived for response to the ordinary questions asked by children of their seniors. Lady Falmouth in her preface modestly disclaims originality for her teachings, and it is true that all standard books on elementary physiology cover much of the ground over which she has gone; at the same time, as far as we know, her methods of presenting physiological facts are quite original, while they are devised in the proper way to arrest the reader's attention. The last sections of the book, entitled "A Parable from Nature," "Life," and "Character Building," form a sort of moral of the "talks," and there is no doubt that children who have been brought up to regard life from the standpoint indicated in these pages will be extremely likely to make good citizens and happy and healthy individuals. There is an adequate glossary, and the pictures fulfil their proper function in that they really elucidate the text.

The Land of Promises. By STANLEY PORTAL HYATT. London: T. Werner Laurie. 1911. Pp. 293. Price 6*s.* net.—In this, his latest novel, Mr. Stanley Hyatt in no way falls short of the vivid description and terse diction of his previous performances, but in "The Land of Promises" his dislike for methods which have been used in the government and development of South Africa, and his objection to certain forms of missionary work, lead to the introduction of details which impair an otherwise good story well told. The story centres round a problem in heredity, and shows how an inherited predisposition may be subdued, and perhaps conquered, by early training and environment, especially when helped by an inbred sense of honour, by self-reliance, and by the love of a noble woman. The reverse of the picture is also well brought out. Hatred of hypocrisy sometimes leads the author to be harsh in his judgments, but allowing for this the novel is well worth reading.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—On June 7th, 1811, occurred the birth of Sir James Y. Simpson, and the present being the centenary year the June issue of this magazine is mainly devoted to reminiscences and appreciations of the great obstetrician. Personal recollections are contributed by Miss Eve Blantyre Simpson, his daughter, and by Sir

Alexander R. Simpson, his nephew. Dr. Joseph Anderson, professor of antiquities in the Royal Scottish Academy, discusses Simpson's work in archæology; Sir Halliday Croom writes on his influence on the progress of obstetrics; and Dr. A. H. Freeland Barbour on his position as a gynæcologist. Dr. D. Berry Hart deals with his work in the introduction of anæsthetics and with other of his scientific writings, while Dr. J. W. Ballantyne writes of his contributions to antenatal pathology. The same number of this journal contains Sir Alexander R. Simpson's address to the Harveian Society entitled, "Life and its Epiphanies." Dr. D. Berry Hart contributes an important paper on Diffuse Adenoma of the Vagina, of which Dr. F. W. N. Haultain records an instance in a separate contribution. Dr. R. W. Johnstone writes on eclampsia originating in the puerperium, which he regards as due to a poison of feeble potency, unable to act until the nervous system is worn out by the strain of labour.

Dublin Journal of Medical Science.—In the June number Mr. J. Spencer Sheill records some striking cases both of failure and success occurring in his experience. Dr. W. M. Crofton discusses the etiology and treatment of diabetes mellitus, which he regards as due to the absence of a co-ferment manufactured by the pancreas, and accordingly treats by preparations of this gland. Dr. G. Arbour Stephens discusses the *modus operandi* of vaccine treatment and suggests an analogy with reverse fermentation.

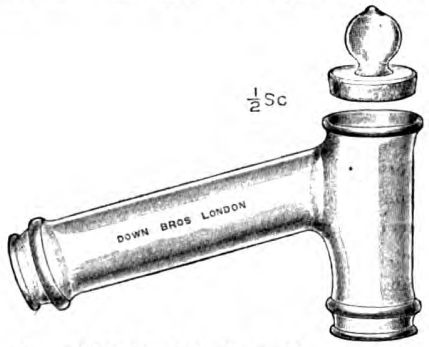
Birmingham Medical Review.—In the issue dated June 15th Dr. Thomas Wilson writes in praise of Pfannenstiel's suprapubic transverse fascial incision for operations on the pelvic organs. Dr. T. Gwynne Maitland deals with the therapeutics of suggestion, and concludes that it is impossible to introduce this method as a branch of recognised medical treatment.

Annali di Medicina Navale e Coloniale. Vol. I. Fasc. III. March, 1911.—This issue, which, despite its date, has only just reached us, contains an interesting account by Dr. G. Saccone of the precautions taken to prevent cholera infection among emigrants proceeding from Naples to South America last autumn when, it will be remembered, a sharp outbreak of this disease occurred in Southern Italy. The *Marsala* was used as a quarantine vessel, provided with all requisites for disinfection and with a bacteriological laboratory for diagnostic purposes; she was anchored close to the disinfecting station at the Mole of San Vincenzo in the port of Naples for four months; the total number of emigrants received is not stated, but although very many came from infected places, and about 1 per cent. were found to be carriers of the cholera spirillum, not a single case of the disease occurred on board owing to the thoroughness of the precautions adopted. Professor T. Rosati writes on the formation of a "sanitary conscience" among the people, beginning in the school, and developed in military employ, as well as in the extensive emigrant service. Three cases of "climatic bubo" (so-called) on board ship are related by Dr. G. Serra, and their relation to pestis bubonica (present in South American ports that had been visited) discussed. There is also an account of the plague epidemic in Manchuria by Dr. di Giura, who, dating from Peking at the end of February, states *inter alia* that serum and vaccine treatment had had negative results, and that inoculation was favoured by most Manchurian practitioners. Haffkine's treatment had not had such good results as in India; the best preventive measures were those that attacked the infection at its seat of origin—e.g., burning corpses and destruction of infected dwellings. Although plague symptoms were noted in rats and other animals, these were not considered to have any importance in spreading the epidemic.

New Inventions.

A NEW COLOSTOMY TUBE.

THE tube here illustrated has been made for me by Messrs. Down Bros., Limited, of St. Thomas's-street, London, S.E. A purse-string suture is run in the wall of the intestine which requires opening, and drawn tight over the lower end of the tube, the ends being tied and again bound round the end of the intestine and tube. The wound is then closed and



dressed, after which the tube is gently raised, the stopper removed, a knife or cautery inserted, and the intestinal wall incised, being steadied by a sharp hook if necessary. There is no hæmorrhage as it is controlled by the ligature surrounding the bowel and tube. In this way absolute asepsis is preserved till after the wound is dressed and the tube fixed.

J. C. F. D. VAUGHAN,
Surgeon, R.N.

Ashburton.

ANTHRAX AT BRADFORD.—At a meeting of the Anthrax Investigation Board, which was held at the Bradford Chamber of Commerce on June 29th, it was reported that since May 15th three cases of anthrax had occurred: two of malignant pustule, both of which recovered, and one of the pulmonary variety, which ended fatally. Dr. F. W. Eurich said that a further series of experiments had been conducted with a view of determining whether anthrax germs would spread within a bale when water-damaged, and it had been found that though the bacillus might multiply locally, it did not pass deeper than about 1 c.m. into the surrounding material. In a discussion on the three reported cases the necessity for the elimination of all blood-stained material during the sorting process was emphasised, and the board decided to urge through the press the advisability of sorters in their own interests picking out all such material. Since the meeting a case of anthrax has occurred at Knayton, near Thirsk, the patient having presumably contracted the disease as the result of skinning a beast which was recently slaughtered and afterwards found to be suffering from anthrax. The patient is progressing favourably.

DONATIONS AND BEQUESTS.—By the will of the late Mrs. Ellinor Arbuthnot the testatrix bequeathed £500 each to King Edward's Hospital Fund, the Guildford County Hospital, and the East London Nursing Fund.—The late Miss Maria Goodenough Cox has bequeathed £3000 to the Taunton and Somerset Hospital.—Among other bequests the late Mr. Henry Kirk has left £5000 upon trust to pay the income to the Nottingham General Hospital, £1000 to the Nottingham General Dispensary, £300 each to the Nottingham Blind Institution, the Nottingham Children's Hospital, the Nottingham Hospital for Women, the Mablethorpe Convalescent Home, and the Skegness Convalescent Home, and £200 to the Nottingham Eye Infirmary.—The late Mrs. Mary Ann Routledge has bequeathed £1200 to the York County Hospital and £200 to the York Dispensary.—Under the will of Mr. William Jones the testator left £1000 each to the Southport Infirmary and the Southport Convalescent Home and Sea-Bathing Infirmary.—The late Mr. James Clason Harvie has left by will, among other large bequests, £3000 each to the Edinburgh Royal Infirmary and the Glasgow Royal Infirmary, and £1000 to the Royal Hospital for Sick Children, Glasgow.

THE LANCET.

LONDON: SATURDAY, JULY 8, 1911.

The National Insurance Bill.

WE have received again this week letters from correspondents of all descriptions dealing with the National Insurance Bill, but there does not seem to us any necessity for publishing them save one or two, for no new points were brought forward by the writers. All very strongly supported some or other of the heterogeneous objections made by previous correspondents, and all in so many words, or by implication, agreed that time is wanted to consider the Bill. The outstanding lesson to be drawn on every side, and from every expression of opinion upon the Bill, is the necessity for time to discuss the varied and important issues raised by it—and this not only in connexion with the medical profession but in connexion with society at large. It seems now to be well known that many Members of Parliament, either on general grounds or special grounds, hold the view that the Bill is essentially one that should not be hustled through its various stages at all costs, to be set right somehow or other by new legislation later. We can quite understand the anxiety of the Government to have a measure which was received by the representatives of the people upon its introduction to their notice with such generous enthusiasm on both sides of the House. The Government may well consider that the people have practically commissioned the Executive to make the Bill into an Act with the shortest delay possible. Further, it may be pleaded that, as there are many interests involved of the sort which necessarily suffer during periods of anxiety, uncertainty, and transition, it is for the good of the majority that a definite solution of the difficulties should be arrived at with the minimum of delay. We can follow these arguments for expedition quite easily, but they are unsatisfactory, and have been so recognised by the Government, who suspended the Standing Orders of the House on Wednesday night so as to prevent interruption of the debate.

All political parties allow that a considerable number of men, for strong if conflicting reasons, regard with apprehension any rushing-through tactics in connexion with a measure which is going to cost the State an enormous sum of money and affect the relations of employer and employee in thousands of directions. That section of the public which takes due thought on political affairs, without being wholly subservient to party tactics, is probably on the side of the medical profession in hoping that there will be no stifling of debate on the measure, and no precautions spared lest clauses should find their way into the Bill which may be worked in opposition to interests the position of which has not been thoroughly ascertained. No one suggests that time, talent, ingenuity, and experience have not been employed in framing the measure—the public as well as the popular legislative assembly agree here—but there is a good deal of evidence that the information received by those responsible for framing it has not been properly sifted, and that deductions from that information have been arbitrarily made, and have resulted in unforeseen troubles. The medical profession, we think, has been improperly depicted by the lay press as being the only body which regards with apprehension the working of the measure as detailed in the existing proposals. Of course, no one can provide a scheme for medical benefits without medical men. Hence alike the pre-eminent claim of our profession for fair treatment and the fact that our unanimously expressed opinions of resentment at the Bill have attracted such serious consideration. Medical men cannot be dispensed with. But it should be thoroughly impressed upon our readers, and through them upon the public, that medical men are not alone in asking that reasonable time should be accorded for the adjustment of obvious and grave defects. There are many others whose connexion with proposals for sickness and unemployment insurance is very vital, and who will support on strong grounds the growing feeling against any hurry in passing the Bill.

The Chancellor of the Exchequer is still considering the sixfold terms which were formulated by the meeting of Representatives of the British Medical Association on June 1st and which have been endorsed by a large proportion of the Association. The terms are admitted not to embody the whole of the demands of the medical profession, and so far Mr. LLOYD GEORGE has yielded some things that he did not seem prepared to yield at the beginning. In the personal assurances which we were authorised to publish from the Chancellor as long ago as May 20th there will be found a promise, or at least an indication of a promise, to do the two things which it has been publicly announced he will do—namely, to allow adequate representation of the medical profession upon the authoritative bodies created under the Bill, and to make definite provision in the Bill, with a reasonable reservation, for a free choice of doctor. Six weeks ago Mr. LLOYD GEORGE expressed himself as being willing to go thus far, not in so much detail, but certainly by implication; it seems that he has now promised to go farther. In Committee of the whole House on Wednesday an amendment was accepted limiting the class of voluntary contributors to persons whose income does not exceed £160. The Chancellor is also considering the introduction of an amendment securing that persons who can pay fees to medical men, although beneficiaries under the Bill, should continue to pay fees, their benefits being accumulated against future illness.

Section of the Posterior Roots of the Spinal Nerves.

It is only comparatively recently that any surgeon has endeavoured to apply the knowledge gained by the physiologists to the treatment of disease. In the present issue of THE LANCET appear two papers of no small importance on the surgery of the nerve roots. One of the papers is by Professor FÖRSTER of Breslau, one of the pioneers of the

branch of surgery, and the other by Mr. E. W. HEY GROVES of Bristol, who has contributed some important cases.

All the operations have consisted in division of the posterior nerve roots of some of the spinal nerves, and the first question was, What affections would be likely to be benefited by cutting off the sensory impulses from the affected area? The natural answer would be that cases in which there was present intense pain would be most suitable, for it might be thought that if there were pain in a part, and the sensory nerve to that part were divided, the pain would cease completely and at once. In this instance, as in so many others, the result differs considerably from what might have been expected. It is true that some cases have been recorded in which severe peripheral pain has been materially and permanently relieved by section of the posterior nerve roots, but these successful cases form only a small minority of those in which this operation has been performed for pain. In a case in which the interference with sensation was so complete that subsequently it was possible to excise the knee without any anæsthetic, much of the pain in the limb persisted. It is possible that in a certain proportion of these cases the division of the sensory nerve roots has not been complete, but this explanation can apply to only a small number of the failures, and it is likely that the explanation put forward by Mr. HEY GROVES will serve to explain correctly many of the others. In one of his cases, in which he had divided the posterior roots of the fourth and fifth lumbar and the first, second and third sacral nerves, some temporary relief from pain occurred, but later pain returned in a very severe form, and then the patient had recurrent attacks of mania. The pain was better during the maniacal attacks, but it came back as the mental condition improved. In this case, and not unlikely in some of the other unsuccessful cases, it is very probable that the pain was in part at least of psychical origin. It is clear that in such a condition as this the division of the sensory roots cannot do much good. Patients suffering from the characteristic "crises" of locomotor ataxia would not at first sight appear to be suitable for this treatment, but experience has shown that much amelioration is sometimes attainable by section of the posterior roots, and in some few cases the improvement has been so great that the patient has been able to return to his occupation. The suggestion of this method of treatment is due to Professor FÖRSTER, and he performed the first operation in 1908. Up to the present time the operation has been performed in 25 cases. In three of these the operation proved fatal. Of the remaining 22 cases 2 were not benefited, and in 7 there was a relapse, but in 13 cases the result can be considered as satisfactory, though in some of them but little time has elapsed since the operation.

In yet a third form of disease this operation has been employed. In certain cases of spastic paralysis, associated with disease of the pyramidal tract, division of the posterior nerve roots has been employed, and with remarkable success in suitable instances. The explanation that has been given of this beneficial result is this. In the pyramidal tract there are two kinds of fibres—those which carry the motor impulses and those called the inhibitory fibres, which check the sensory stimuli coming by the sensory nerve roots. As a result of the damage of the inhibitory fibres the sensory impulses act unrestrainedly on the nerve centres and a reflex spasm results. If then the afferent impulses be cut off the spasms will disappear. It is, however, essential that the fibres bearing the motor impulses must be intact or at all events not much damaged. It is also clear that the operation cannot be of the least benefit in cases where the spasm is of central origin, as in chorea. The operation has been performed in more than 60 cases, and the results are on the whole very interesting and wonderfully satisfactory, considering the almost hopeless condition of most of the patients. Spasm is in all these cases definitely relieved, and if the pyramidal tract is still fairly undamaged great improvement in motility follows. Mr. HEY GROVES has suggested the injection of a very weak solution of adrenalin just before the operation, and this renders the operation almost bloodless, and thus its duration is markedly shortened.

Only a little more than 20 years have elapsed since the operation of division of the posterior nerve roots was first performed, and it is very much less than this since the number of cases has been at all great, so that any verdict uttered now must at least be tentative, but at least this may be said. The operation in skilled hands has but a small mortality; if the issue in cases where it has been performed for the relief of pain has been very disappointing, in cases of gastric crises results have been achieved which surpass what can be attained by other methods of treatment, and in most cases some improvement follows. It is, however, in certain cases of spastic paralysis that the best results are obtainable, though the cases must be carefully chosen. We shall await with interest the publication of further instances of the performance of this operation, which will enable us to form more exact ideas as to the cases in which it can confidently be recommended. With the improvement of technique the mortality should diminish, though even now it is not very high, and as the operation offers success in cases otherwise hopeless it is deserving of an extended trial.

Medical Administration in Trinidad: The Vindication of Dr. H. L. Clare.

ON two previous occasions we have had to refer to a matter that has greatly—and, as it would now appear, unduly—disturbed the equilibrium of the medico-social atmosphere of Trinidad. In THE LANCET of Sept. 17th, 1910, we chronicled the sitting of a Commission appointed by the Governor of that colony to inquire into certain alleged derelictions of duty, administrative inefficiency, and improper conduct towards his subordinates on the part of Dr. H. L. CLARE, surgeon-general of the colony. In our issue of Feb. 4th, 1911, we briefly reviewed the voluminous report of that Commission, which sat for 27 days, counsel being engaged on either side, and stated that "everything that could possibly be said or written on the matter appears to have been written or said, not once, but many times over." We added: "We are sincerely glad to hear that the chairman of the Commission, although not able to acquit Dr.

CLARE of failings in administrative capacity, finds no proof of any lack of honour or integrity in his character."

This report, with the minutes of evidence and documents, has now been reviewed by the Secretary of State for the Colonies, Mr. HARCOURT, and his decision thereon is expressed in a letter dated June 6th, 1911, and addressed to the Governor of Trinidad, Sir G. R. LE HUNTE, K.C.M.G. The Colonial Secretary, at the outset, expresses the opinion, with which we heartily agree, that it would have been better, in fairness to Dr. CLARE, if an independent medical expert had been appointed as one of the members of the Commission. The need of such an expert Mr. HARCOURT finds demonstrated by the frequency with which the Commission felt itself unable to advise on certain points without professional assistance. Two main facts, the Colonial Secretary says, emerge in the report: 1. That the allegations made against Dr. CLARE in the Legislative Council of Trinidad are not those on which the Commission reported, but that the Commission decided to hear the evidence first, and then to formulate the charges. 2. That Charges II. to VI. inclusive, as formulated by the Commission, and covering those matters relating to the internal administration of the Medical Department of the Colony, substantially broke down on hearing, from which fact Mr. HARCOURT arrives at the conclusion that these allegations must have been made on the slightest foundation and "reflect little credit on those who raised an agitation concerning matters with which they had such an imperfect acquaintance." That leaves only Charges I. and VII. for detailed consideration. With regard to Charge I., the Commissioners consider Dr. CLARE'S procedure as to notification of quarantinable disease based on a mistaken principle. This is a suggestion that the supervising authority should be debarred from waiting for opportunities of making a scientific diagnosis, and we are not surprised to find the Local Government Board in accord with Dr. CLARE'S attitude and procedure. Charge VII. not only raised the question as to professional treatment in a certain case, but also elicited "a distinct suggestion in the several reports of the Commissioners that Dr. CLARE'S conduct to Dr. E. DE VERTEUIL was marked by bad faith." The Secretary for the Colonies, noting that a *primâ facie* case had been made out on these two charges, thought it necessary to obtain expert advice, the more so in view of the general distrust that had arisen concerning the fulfilment of the obligations of Trinidad under the West Indian Sanitary Convention and its present position as the headquarters of the Intercolonial Mail Service. He therefore selected the Local Government Board as the highest authority on quarantine matters, and submitted to them for their opinion the unsettled points in Charges I. and VII., together with all the documents in the case. The correspondence between the Colonial Secretary and the Local Government Board is appended to Mr. HARCOURT'S letter, and makes quite satisfactory reading for those who consider that Dr. CLARE has been very unfairly treated. In the words of the Local Government Board, "it appears from the evidence that in certain instances he [Dr. CLARE] refused to recognise the case as one of plague on clinical evidence alone, and considered bacteriological evidence necessary to justify definite diagnosis. The Board are advised that in so acting, Dr. CLARE followed the customary practice, and would, if he had any doubt as to the true nature of the disease, have acted wrongly in doing otherwise." As regards yellow fever, respecting which bacteriological evidence is not available, Dr. CLARE is held by the Local Government Board to have acted rightly in endeavouring to satisfy himself, by inquiry, as to whether the cases, in which he doubted the correctness of the diagnosis, were or were not in fact cases of the disease. Therefore, Mr. HARCOURT says, the conclusions of the Commissioners on the first charge against Dr. CLARE cannot be upheld. With regard to the seventh charge, that Dr. CLARE tried to coerce his subordinate into changing his opinion as to the real nature of a certain case, and, having failed, accused him of being guilty of the patient's death, a charge which was characterised by one of the Commissioners, Lieutenant-Colonel SWAIN, as "absolutely false and unfounded," this charge was withdrawn. It was found that Dr. CLARE acted improperly in failing to forward to the Governor of Trinidad Dr. SEHEULT'S covering letter, in circumstances which are fully set out in the report of the Commission. After devoting much attention to the point the Colonial Secretary concludes that here Dr. CLARE committed an error of judgment, but that there was no intention on his part to deceive.

The Colonial Secretary thus sums up: "As the Commissioners' report is favourable to Dr. CLARE in regard to Charges II. to VI., as the Local Government Board have upheld his procedure in the matters which fell under Charge I., and as Charge VII. results only in a decision that his judgment has been at fault, it would seem natural to conclude that there was insufficient justification for so laborious an investigation. So far as Dr. CLARE is personally concerned I must say unhesitatingly that this is the case. He will be able to return to the colony with the assurance that, after the most searching inquiry, nothing has been proved against his personal honour, or against his ability in his profession. This, however, will hardly make up for the heavy strain which the inquiry will have entailed upon him, and in the circumstances I consider that Dr. CLARE is fully entitled to be indemnified for the expenses which he was forced to incur through the appointment of the Commission and the procedure adopted." Mr. HARCOURT expresses the hope, from a wider point of view, that the inquiry will dissipate the mistrust for some time existent in neighbouring communities as to the inadequacy of the practice of the Trinidad administration in ascertaining and notifying cases of infectious disease. Dr. CLARE, therefore, is free to return to his post with his honour vindicated and his personal expenses, to some extent at least, indemnified, but neither can fully compensate him for the mental strain that must have been thrown upon him by this bitter attack. And bitter is the only word to describe it. After perusing again the closing vituperation of the Hon. L. A. WHARTON, who appears to have regarded himself as conducting a prosecution, we see that no such language should have been tolerated in a Commission of Inquiry. As we said previously in this regard, the dispassionate form of investigation, or commission, to which we are accustomed at home, in which the object is simply to get

at the facts of the case, not to secure a forensic victory for one side or another, is much to be preferred. We trust, however, that the complete vindication of Dr. CLARE will result in a general amnesty between the parties recently in conflict.

Annotations.

"Ne quid nimis."

THE NOMENCLATURE OF MALTA FEVER.

WE learn that the Governor of Malta has made representations to the Secretary of State for the Colonies with regard to the use of the term "Malta fever." The Governor points out that the disease in question, which is called "Mediterranean fever" by some authorities and "undulant fever," or "undulating fever," by others, so far from being peculiar to Malta, occurs all over the Mediterranean littoral, being found in Egypt, Cyprus, Greece, Crete, Sicily, Italy, France, Spain, Algeria, Tunis, and Tripoli, as well as in other countries such as India and South and Central Africa, which do not border on the Mediterranean sea. He urges that the name "Malta fever" is inappropriate and likely to operate to the disadvantage of the island by conveying the impression that Malta is the only place where the fever prevails. The Governor's views have been brought by the Secretary of State to the notice of the London and Liverpool Schools of Tropical Medicine and the Academy of Medicine in France, as well as the War Office and the Admiralty, with the result that all these institutions have agreed to abandon the use of the term "Malta fever." This commendable action raises once again the old question of the want of uniformity in the nomenclature of diseases. The Royal College of Physicians of London grappled more or less successfully with this problem some years ago, and their nomenclature was adopted by the Registrar-General upon death certificates; but medical writers and speakers have never really paid much serious attention to these rulings, and many old muddles remain. The task of reform seems almost too hard. Even if a definite uniform plan based on pathology, as in poliomyelitis, or on some leading characteristic, as in infantile palsy, were adopted by all the teaching and examining bodies, and insisted upon to the utmost of their powers, there are many diseases whose old and perhaps stupid names would die very hard. As a matter of fact, Malta or Mediterranean fever stands almost alone in the list of diseases named after places. Texas fever, Delhi boil, and Guinea worm seem to be its main congeners. Roman fever as a term for malaria is not used in medicine, and rickets is not known in this country as "the English disease." We sympathise with the inhabitants of the island of Malta in their protest.

THE SALE OF SECRET REMEDIES.

THE Home Secretary's promise, or rather half-promise, to appoint a Select Committee to consider the conditions of the sale of "patent medicines"[1] will be welcomed by the medical profession and, in all likelihood, by the vast majority of pharmacists. For a long period the methods employed by some manufacturers of secret remedies have been a scandal, and an official inquiry into these methods and into the composition of the medicines cannot but lead to good results. Mr. Churchill's statement will not have taken the manufacturers unawares. They were, in fact, prepared to expect an inquiry at an earlier date, for Lord Gladstone, who preceded Mr. Churchill as Home Secretary, intimated that he considered the appointment of a committee for this purpose desirable. So large are the interests threatened that the proprietors of secret remedies are sure to fight strenuously in their own defence, and it therefore behoves those whose desire it is to check the sale of harmful nostrums to be prepared with an irresistible attack. During the year ending March 31st, 1910, the latest period for which the figures are available, the revenue from medicine stamp duty was £313,114, and during the ten years ending at the same date the revenue derived from this source reached a total of over £3,000,000 sterling, which means that during the decennial period the British public spent between £20,000,000 and £25,000,000 on medicines subject to duty. These figures afford some idea of the vastness of the interests affected by the proposed inquiry. Apart from the individual influence which some manufacturers will be able to exert, it is important to note that, as a class, they are well organised. It is interesting to observe that in the United States of America, where the public is afforded some degree of protection against fraudulent and harmful nostrums, it is intended to strengthen the law relating to the sale of these articles. In a recent special message to Congress President Taft referred to the failure of the Pure Food and Drugs Act to give anything like adequate protection to the public, and strongly recommended Congress to pass a measure of legislation the effect of which would be to overrule recent decisions of the courts by which the intentions of the Act have been frustrated.

[1] THE LANCET, July 1st, 1911, p. 62.

BIOT'S BREATHING.

IN 1876 Camille Biot published an article on Cheyne-Stokes respiration in the *Lyon Médical* showing pneumatographic tracings taken from a boy aged 16 years and suffering from tuberculous meningitis. These differed from Cheyne-Stokes respiration in that, instead of the respirations gradually diminishing and increasing before and after the pause, they became deep and dyspnœic and corresponded to a deep sigh. Two years later, in a further study of the subject, he quoted from a number of authorities, including Trousseau, to show that the characteristic respiration of meningitis, especially of the tuberculous form, is of this type. However, this form of dyspnœa has received little attention from subsequent writers. In the *American Journal of Medical Sciences* for March Professor Lewis A. Conner has published an important paper on Biot's breathing. During the past two years he has made graphic study of pathological types of breathing and encountered seven typical cases of Biot's type of breathing. In six cases the patient was suffering from meningitis. He has found that its characteristics are as follows: 1. Periods of apnœa which vary in length and occur at irregular intervals. 2. Constant irregularity in the rhythm and depth of individual respirations. 3. The frequent occurrence of deep sighs. 4. In spite of the variation of the depth of inspiration the position of the chest at the end of expiration, remained constant. This seemed to be due to the fact that the expiratory act was purely passive, the active muscular expiration, frequently present in various forms of dyspnœa, being absent. In contrast to this the breathing in a case of fatal anuria showed great irregularity in the level of expiration, the ascending (expiratory) limb of the tracing being carried above the mean expiratory level in consequence of active muscular efforts during expiration. Otherwise the breathing corresponded to Biot's type. In six out of the seven cases of Biot's breathing the disease was meningitis, and in the seventh some intracranial complication of suppurative mastoiditis, possibly meningitis. In 24 other cases of meningitis Biot's breathing was never detected. It was thus observed in 20 per cent. of the cases of meningitis. The scanty literature of the

subject shows that Biot's breathing is supposed to occur not only in meningitis, but in other cerebral conditions. It is therefore sometimes described as "cerebral breathing." In three of the present cases the patients were infants under the age of 2 years; in two they were children of the age of 8 years; and in two they were adults. Of the six proved cases of meningitis four were tuberculous, one was due to the streptococcus pyogenes, and one to the diplococcus intracellularis. In a great variety of other diseases studied, including a number of cerebral ones, such as hæmorrhage, thrombosis, syphilis, and various forms of coma, no case of Biot's breathing was found. In four of the cases in which Biot's breathing was present it was observed a few days after the onset of the symptoms. It may therefore be an early and important sign of meningitis. Its occurrence seems to bear no special relation to the state of the pulse (whether rapid, slow, or irregular), or indeed to the presence or absence of any other symptom. It was observed in cases of slight drowsiness as well as of deep coma. Biot's breathing may be further contrasted with Cheyne-Stokes breathing. The dominant feature of the latter is the rhythmic succession of periods of dyspnœa and apnœa. The periods of apnœa are uniform in length and occur at regular intervals. The periods or dyspnœa are composed of the same number of respirations, which regularly wax and wane. The characteristic feature of Biot's breathing, on the other hand, is the absence of any sort of rhythm. The periods of apnœa vary in length and occur at irregular intervals, and there is constant irregularity in both rate and depth of the respirations. Such differences seem to point to a different pathogenesis of the two conditions. In a comprehensive study of Cheyne-Stokes respiration Dr. G. A. Gibson of Edinburgh, accepting the conclusions of Marckwald that periodic breathing can occur only when some of the higher brain centres have ceased to exert their influence on the automatic centre of the medulla, has suggested that Cheyne-Stokes breathing may require the total abolition of such influence, and that the meningitic or cerebral type of breathing may result from the irregular discharge of unequal impulses from the higher centres.

HEALTH ADMINISTRATION IN SOUTH AFRICA.

WE learn that two very well-known and efficient medical officers of health in South Africa have lately been informed by the authorities that they are about to be "retrenched"—in other words, that their services will no longer be needed in the important posts which they now hold. Dr. A. J. Gregory is medical officer of health of Cape Colony and Dr. Pratt Yule is medical officer of health of the Free State, and each is to be "retrenched" as from the end of August. In this connexion it is important to recall that the Public Health Amendment Bill, introduced during the first session of the Union Parliament of South Africa, provided for the establishment of a Chief Union Medical Officer, together with such assistant medical officers as might be necessary. This Bill was not passed, but it is believed that the South African Government has not dropped the idea of creating the post of principal medical officer of health for the Union, although it does not see its way to appoint a Minister of Public Health with a separate department, as was urged upon it by various medical authorities. It seems probable that a chief and an assistant medical officer of health for the Union will soon be appointed, and it was generally anticipated in public health circles that Dr. Gregory and Dr. Pratt Yule respectively would be selected for these two important positions, since their claims are exceptionally strong. There seems to be a firm conviction that no medical officer in South Africa is so well fitted by experience and ability for the chief officership as Dr. Gregory. In these circumstances the news of Dr. Gregory's approaching retirement from his present post on a pension has come as a shock to a large number of medical men and other authorities interested in the national health of the Union, who fear that the Government intends to overlook his undoubted claims. Dr. Gregory's record of past services, contained in the Cape Civil Service List, suggests that it would be a public misfortune for him to be lost to the public health service of that country at the most critical stage in its history.

GOVERNMENTS AND ECONOMIC MEDICINE.

THE banquet and reception given to President Taft by the Medical Club of Philadelphia,[1] at which more than 1000 medical men were present, has a significance reaching far beyond the United States of America. The function and the speeches of which it was the occasion emphasise the increasing recognition, not merely *pro formâ*, but with actual appreciation due to intimate personal knowledge, by the governing powers of the economic and social significance of public hygiene and preventive medicine. The speech of Mr. Taft particularly was replete with an intimate knowledge made possible only by his close association with the medical profession in his public capacities as former Governor-General of the Philippines, Governor of Cuba and Secretary of War, and his personal observation of the effects of sanitation in Porto Rico and in the Canal zone of the Isthmus of Panama. He spoke of the fact that the cleaning up of Havana, while useful in the prevention of other diseases, had little or no effect in preventing yellow fever until Major Walter Reed and his colleagues demonstrated the connexion between that disease and the stegomyia, which fact was promptly applied by Colonel Gorgas, of the Army Medical Corps, with the result that the disease has been practically banished from Havana. In like manner uncinariasis, or tropical anæmia, is in a fair way of banishment from Porto Rico; while in the Philippines cholera has been greatly reduced, small-pox (which had previously flourished there in virulent type) has been practically stamped out, bubonic plague has had its terrors removed, the injurious effects of malaria have been moderated, and even amœbic dysentery is being brought under control. Removal of lepers to the island of Culion has reduced the new cases of leprosy in the Philippines to 16 per cent. of what they were formerly, and beri-beri has been practically stamped out of those islands. Moreover, the study of the dejecta of the native Filipinos has shown that the intestinal flora has been largely responsible for the enfeebled condition of that race, which by proper treatment founded on this knowledge may be greatly strengthened. As to the Canal zone of the Isthmus of Panama, what was formerly a pest-ridden zone has been converted into a pleasant and healthful place to live in. "Colonel Gorgas," said President Taft, "stamped out yellow fever, so that for now more than four years there has not been a case on the Isthmus, and he reduced the malignancy and extent of malaria on the Isthmus to such a point that the percentage of deaths in the foreign population of the zone is considerably less than in our large cities." Another evidence of the vast improvement in sanitation cited by President Taft is the fact that the United States now has a division of 18,000 soldiers in Texas and California living under canvas for two months, "in a country soaked with rain and deep with profanity-provoking mud"; yet the percentage of sick men is less than it was in the posts from which these men were mobilised. During the Spanish-American war, of the volunteer regiments mobilised

[1] President Taft and the Medical Profession, American Medical Association, 1911.

90 per cent. became infected with typhoid fever within eight weeks from the date of mobilisation, yet to-day, in the same period after mobilisation, but with modern health regulations and antityphoid vaccination, only one case of typhoid fever has appeared, and that in the case of a teamster who was not vaccinated. A large part of the research work, though not all, as a result of which these splendid results have been attained, has been done by army medical officers, and President Taft concluded by congratulating the medical profession at large that "they have had the opportunity, and have seized it, to make such progress in relieving the suffering of the human race and in becoming in so conspicuous a way the benefactors of mankind." In these days a movement of real progress rapidly spreads from one nation to another, and if the example set by the Medical Club of Philadelphia in bringing into close touch the administrative authorities of the country with the economic work of its medical profession, military, naval, and civil, should so spread, it will have deserved the thanks of all peoples as well as of the medical profession.

NURSES AND THE WORKMEN'S COMPENSATION ACT.

A MEDICAL man has recently inquired whether a patient employing a private nurse (not attached to any institution and therefore not already insured by an employer) is liable to compensate her if she meets with an accident in the course of her service with him. The question was evidently intended to refer to the ordinary circumstances of nursing a case of temporary illness, where the nurse remains for a short time, perhaps for a few days only, in the patient's employment; and our correspondent also alluded to the obvious inconvenience to the patient of effecting insurance under such conditions, suggesting that the difficulty might be met by the nurse insuring herself "as if she were her own employer." We may point out here that the question of insurance is not one with which the Workmen's Compensation Act, 1906, concerns itself. It provides that employers shall pay compensation upon a prescribed scale to persons employed by them, in the event of such persons meeting with accidents and claiming such compensation, but the employers are left to decide for themselves whether they shall protect themselves against loss by insurance or not. There can be little doubt that a nurse attending a case in a private family in the ordinary circumstances inquired about by our correspondent comes within the definition of "a person who has entered into or works under a contract of service or apprenticeship with an employer, whether by way of manual labour, clerical work, or otherwise," and that such exceptions as are provided for do not in ordinary cases, at any rate, apply to nurses. Equally there can be no question that a nurse's calling exposes her to a risk of accident rather more than is the case with many employed persons. Her risk, at any rate, is greater than that of most domestic servants. These latter are, as a rule, insured by their employers, but probably the insurance of the nurse, who in the sudden emergency of illness becomes one of the employed, is rarely thought of. The suggestion that she should insure herself does not, strictly speaking, meet the difficulty. There is nothing to prevent a nurse from insuring herself against accident, illness, or anything else, and the nature of her occupation makes it obvious that this is an exceedingly prudent and proper thing for her to do. It would not, however, protect her employer if she were to do so, even though she were to tell him that she was insured on entering his house and to undertake to bring no claim for compensation against him, because the Act provides that there shall be no "contracting out" of its provisions. Of course, a nurse who undertook to bring no claim and then took legal proceedings to obtain compensation for accidental injury would be acting dishonourably, but that is another matter, and the opportunity for doing so would rarely arise, as the employer who was prudent enough to take into consideration the question of possible accidents when engaging a nurse would hardly be so foolish as to be a party to a contract which everyone knows to be legally void. To refer again to the question of our correspondent, which he confines to the case of a nurse "not attached to an institution," we do not limit our view of the patient's liability to nurses who, so to speak, earn their living as "free-lances." Nurses may sometimes go out to attend cases under such conditions that the institution employing them is, and remains, liable to compensate them for accidents. There must, however, be a large proportion of instances in which the nurse may acknowledge the authority of an institution which to some extent controls her conduct and is responsible for her welfare, but in which she is in fact temporarily in the service of a patient who, while engaging her through the institution, becomes her employer quite sufficiently to give her the right to claim against him. In the circumstances we venture the opinion that a thoroughly prudent patient would insure his nurse and that an obliging medical adviser might earn his gratitude by recommending him to do so. We are not aware of any special policies issued for such occasions by insurance companies, but they may exist, and in any case could easily be devised to meet exigencies which so frequently arise. The amount that they would add to the ordinary expenses of medical and nursing attendance in illness would be comparatively small, and they would provide against contingencies which when they occur may be of a serious character.

THE NECROPSY OF NAPOLEON I.

SEVERAL of our correspondents have alluded recently to the pathological conditions which may or may not have largely influenced some of the dramatic events of the career of that superlatively great man, Napoleon. Some, if little, light is thrown on the subject of Napoleon's health by the description of his necropsy in the well-known work of Dr. Arnott, "An Account of the Last Illness, Decease, and Post-mortem Appearances of Napoleon Bonaparte, to which is added a letter to Lieutenant-General Sir Hudson Lowe, K.C.B., etc., giving a Succinct Statement of Napoleon Bonaparte's Disease and Demise" (published by John Murray in 1822). Archibald Arnott, who was an M.D., states in the preface to his little book, that "*no* other English medical person saw him in his death-bed sickness." The ex-Emperor, indeed, would only receive the professional visits of Professor Antomarchi and of Arnott, and he went so far, we are told by the latter, as to extract a promise from his "family," or *entourage*, that if at any time he became insensible no other medical man should be called in. Arnott confesses that his notes had always been written in haste, "not with the most distant view of their ever meeting the eye of the public." Nevertheless, these hasty private notes, which, reprinted, only fill two columns in a small gazette,[1] are now a chief authority on the post-mortem appearances of one of the greatest figures of the last century. We reprint the "Report of Appearances on the Dissection of the Body of Napoleon Bonaparte" and leave our readers to draw what conclusions they may therefrom. "On a superficial view the body appeared very fat, which state was confirmed by the first incision down its centre, where the fat was upwards of one inch thick over the sternum, and one inch and a half over the abdomen. On cutting through the cartilages of the ribs, and exposing the

[1] Reprinted in John Bull, Oct. 13th, 1822.

cavity of the thorax, a trifling adhesion of the left pleura to the pleura costalis was found; about three ounces of reddish fluid were contained in the left cavity and nearly eight ounces in the right. The lungs were quite sound. The pericardium was natural, and contained about an ounce of fluid. The heart was of the natural size, but thickly covered with fat; the auricles and ventricles exhibited nothing extraordinary, except that the muscular parts appeared rather paler than natural. Upon opening the abdomen the omentum was found remarkably fat; and on opening the stomach that viscus was found the seat of extensive disease; strong adhesions connected the whole superior surface, particularly about the pyloric extremity, to the concave surface of the left lobe of the liver, and on separating these an ulcer, which penetrated the coats of the stomach, was discovered one inch from the pylorus, sufficient to allow the passage of the little finger. The internal surface of the stomach, to nearly its whole extent, was a mass of cancerous disease, or scirrhous portions, advancing to cancer; this was particularly noticed near the pylorus. The cardiac extremity, for a small space near the termination of the œsophagus, was the only part appearing in a healthy state. The stomach was found nearly filled with a large quantity of fluid, resembling coffee grounds. The convex surface of the left lobe of the liver adhered to the diaphragm, but with the exception of the adhesions occasioned by the disease in the stomach no unhealthy appearance presented itself in the liver. The remainder of the abdominal viscera were in a healthy state. A slight peculiarity in the formation of the left kidney was observed." Commenting on this report, of which Arnott was one of the signatories, he expresses surprise "that a person of Napoleon Bonaparte's habits should have been affected with schirrus and cancer of the stomach; a man who was noted for temperance, and never in his life indulged in any excess which could tend to produce such an affection." "It is somewhat remarkable," however, "that he [the Emperor] often said that his father died of scirrhus of the pylorus." His son, of course, died from phthisis at an early age. It is to be noted that no examination of Napoleon's brain is recorded by Arnott.

THE SARDINE.

DIETETIC authorities may well praise the sardine, since, for one thing, it encourages the ingestion of oil, which for a reason difficult to find is very commonly excluded from the diet nowadays. A bland fat affords such an excellent physiological balance to nitrogenous foods that its reasonable use will help us to avoid many ills, and especially those associated with wasting diseases and gouty dispositions. It prevents the overloading of the tissues with nitrogenous waste products and a digestible fat favours nutrition considerably. The sardine supplies also an excellent proportion (25 per cent.) of nitrogenous material, and so it becomes a real and economical food. In addition to this serves digestion follows. Luckily, its preservation in the cooked state in oil precludes contamination, even although it is brought to our shores in the tin. We have examined a great number of samples of tinned sardines, but not once have we been able to find the slightest evidence of metallic contamination or of objectionable preservatives. The tins consist of no worse metals than iron and tin, both of which may be regarded as practically outside the pale of poisonous metals. Oil is, besides, an effective guard against these metals being attacked. Physiologically it counts for very little if the sardine proves to be not a "scientific" sardine and the oil is not the oil of the olive. We have a suspicion that a preference would be exhibited for the genuine sardines and *l'huile d'olive*, but the fishes substituted for the real Sardinia pilchards are, generally speaking, still of the herring family, and the cheaper oil used is wholesome, consisting often of pea-nut oil or sesame or cotton-seed oil, which contain to a large extent the same fatty principles as olive oil. This view must not be regarded for a moment as favouring the practice of substitution in general, while obviously in this case the consumer is not injured nor is he seriously cheated. Neither what we know to be a herring or sprat is a true sardine, and cotton-seed oil is certainly not *l'huile d'olive*. Strict ethical teaching, however, would require some declaration as to the exact nature of the goods. But if that demand were enforced there would soon arise an unnecessary prejudice against the substitutes, which after all are very closely related to the genuine articles, and which are equally palatable and nutritious. If the real sardine were as abundant as its congeners the position might be different. As it is we may be grateful for a plentiful and cheap supply of this appetising morsel, whether sardine, sprat, or herring.

ACUTE ANTERIOR POLIOMYELITIS IN THE DISTRICT OF COLUMBIA.

THE occurrence of an epidemic of infantile paralysis in the District of Columbia during the summer of 1910 led to the appointment of a committee by the President of the Medical Association of the District of Columbia to investigate the incidence and general characters of the disease. This committee has recently issued an interesting report (reprinted from *Washington Medical Annals*, Vol. X., No. 2, May, 1911) of which we have received a copy. Information was received in regard to 506 cases, which are believed to include approximately all those occurring in the District during 1910. Among these there were 16 deaths. Reports were obtained of 246 cases, but in only 150 of these was the date of onset noted. The outbreak began in June and reached its maximum in July and August. There was nothing extraordinary about the temperature during the epidemic, but the rainfall was much less than normal, the summer being an exceptionally dry one. In regard to age, the youngest patient was 4 months old, the oldest 64 years. Of the 246 cases, of which records were obtainable, 217 or 88 per cent. were under 10 years of age. In six instances there occurred two cases in the same family. Seventeen cases gave histories of exposure to acute cases of poliomyelitis, and one gave a history of exposure to a recovered case. In one locality prior to the appearance of anterior poliomyelitis in human beings there occurred an outbreak of a disease associated with paralytic symptoms among ducks and chickens, and a man who performed post-mortem examinations on two ducks with this disease shortly afterwards developed poliomyelitis. Careful laboratory investigations, however, failed to show any relation between the two conditions. The report includes a note of the pathological examination of a fatal case by Dr. Gonzalo R. Lafora. He found slight dilatation of the vessels and thickening of the pia mater. The grey matter appeared reddish with small hæmorrhages. Histologically, infiltration of the vessels with lymphocytes and plasma cells, and the disappearance of ganglion cells in certain parts of the cord, or their degeneration in the anterior horns, as described by previous observers, were confirmed in this case by Dr. Lafora. The occurrence of a large number of "Körnchen" (granular) cells filling the grey matter and surrounding the few remaining ganglion cells was also a striking feature. Plasma cells were also found outside the adventitial spaces of the vessels, and many of them showed karyokinetic processes or possessed two or more nuclei. Most of the macrophages, which sometimes filled the entire anterior horn, were of the mononuclear variety. Certain rod-like cells (Stäbchenzellen) of neuroglial origin were

found, but mast cells, though seen, were very few. Some very small diplococci were seen among the cells infiltrating the grey matter, and also certain formations, without nuclei, which morphologically reminded Dr. Lafora of the encapsulated Leishman-Donovan bodies in kala-azar. Hypertrophic processes occurred in the nucleoli of the ganglion cells. In many of these cells very marked neuronophagy was observed, and in others the Altmann granules were greatly increased in number. The results of the examination of the cerebro-spinal fluid in 11 cases are recorded by Dr. William H. Hough and Dr. Lafora. They examined the fluid chemically and studied the cells by many different methods of staining, since they found that important details were brought out by one method which were not shown by others. They found that the cerebro-spinal fluid was generally clear, that in the early stages of the disease there was usually an increase of pressure, though this was not as a rule pronounced, and that there was an increase in the protein content sufficient to give a positive Nonne-Alpelt and Noguchi butyric-acid reaction. In the earlier stages of the disease there was an increase in the leucocytes, especially the polymorphonuclears. These cells diminished after a few days, and a lymphocytosis with some plasma cells and sometimes a few mast cells replaced the polymorphonuclear increase. The disappearance of the polymorphonuclears was brought about through the phagocytic activity of the macrophages. Körnchen cells, altered lymphocytes, and other mononuclear elements were commonly present in the fluid until after the febrile period. Dr. Hough and Dr. Lafora suggest that the similarity of these characters to those of the fluid in some protozoan diseases is an argument in favour of the protozoan nature of the virus, even though other observers claim that the disease is produced by a much smaller organism. This report affords some interesting information concerning some of the features of this serious disease, and is a useful contribution to the study of its special characters in the epidemic form.

SUPRAPUBIC PROSTATECTOMY IN A PATIENT WITH AN OLD SUPRAPUBIC FISTULA.

IN the *Annales des Maladies des Organes Génito-Urinaires* for May a case of much interest is described by Dr. M. Patel and Dr. G. Cotte of Lyons. The patient was a man, 67 years old, and nine years previously a suprapubic cystostomy had been performed for retention caused by prostatic hypertrophy. The immediate results of that operation had been very good, and when the opening had contracted a little micturition had become very regular. The patient passed urine about every four hours, and he did not suffer from either retention or incontinence. No urine was voided by the urethra. Slowly a ventral hernia had developed immediately above the urinary fistula, and at last it had grown to such a size as to interfere seriously with his work, and he asked to be relieved of the hernia. On examination by the rectum a very large prostate was felt, but a catheter could not be introduced by the urethra. A large ventral hernia above and in front of the pubis was present, and the urinary fistula opened about the middle of the swelling, but, so far as could be ascertained, the bladder formed no part of the hernia. As the hernia interfered so greatly with the patient's work, and as the fistula prevented the use of a truss, it was resolved to operate. It appeared to be essential to a satisfactory result that the urinary fistula should be closed, and that urethral micturition should be re-established. It was found to be impossible to reach the bladder without opening the peritoneum; therefore, a large skin incision having been made, the hernial sac was removed and the peritoneum was sutured. With very great difficulty the fistula, which measured 10 to 12 centimetres in length, was followed down to the bladder, which was contracted and lay deep in the pelvis. The bladder was incised, and the prostate was shelled out. A fortnight later urine began to pass by the urethra, and six weeks later the suprapubic fistula was completely closed. Except for slight contraction at the site of the prostatic urethra, which yielded to dilatation, the result was perfect. A little hernial protrusion still existed at the upper part of the scar, but as the fistula was closed a belt could be worn. The great functional value of the suprapubic fistula in this case was probably due to its length and obliquity, and the successful result of the final operation was in great measure due to the fact that no urinary sepsis was present.

LEGISLATION WITH REGARD TO ANÆSTHETICS.

THE question of legislation in regard to anæsthetics has now been prominent for four years. It has been the subject of a Home Office Departmental Committee inquiry and has been thoroughly discussed by (1) the General Medical Council; (2) the Royal College of Surgeons of England; (3) the British Medical Association; (4) the British Dental Association; (5) the Medico-Legal Society; (6) the British Association for the Advancement of Science; and (7) the Anæsthetics Section of the Royal Society of Medicine. All these bodies have reported in favour of legislation, and a draft Bill to protect the public has received the support of the General Medical Council, and is now at the Home Office. We trust that we may be able to report immediately some action upon all this preparation. Not only the medical profession, but a considerable section of the public, have been expecting the Home Secretary to introduce legislation on the lines suggested in the Bill, and the disappointment that this has not been done has been very real. As pointed out in a recent article in our columns, further necessary reforms in anæsthetics are blocked by reason of this delay in legislation. Is it not possible that the Home Office should make an effort to introduce a Bill this session? We are not without knowledge of the stress of affairs at this moment, but the action would be very welcome. If this is impossible, we hope that the beginning of the next session we may see the measure brought forward. Being a question which has been threshed out in so thorough a manner that upon all its essentials there is, practically speaking, unanimity, it is difficult to see why there should be further delay in providing the public with the protection desired.

NEW VIEWS AS TO THE BACTERIOLOGY AND TREATMENT OF LEPROSY.

IN a supplement published with the *Indian Medical Gazette* for May is an interesting article by Captain T. S. Beauchamp Williams, I.M.S., the results of whose researches, if they are confirmed, will modify our view of leprosy. From cases of leprosy he has grown four different types of organisms which he believes are merely four phases of a pleomorphic streptothrix. The first of these phases described in Captain Williams's paper was a Gram-positive streptothrix, not retaining carbol-fuchsin under treatment with acid. It was grown directly from several patients, both in Persia and in Bombay, and also by sub-culture of the second type of organism, a diphtheroid bacillus, which, like the streptothrix, is not acid-fast. Captain Williams believes that the bacillary form is really the result of very rapid division of the streptothrix, favoured by certain cultural conditions. Both of these forms are convertible by suitable methods of sub-culture into acid-fast micro-organisms in which a streptothrix form and a bacillary form can be observed. One interesting method which was employed was the symbiotic culture of the diphtheroid bacillus with pure

growths of amœbæ; the amœbæ ingested the bacilli and thereby rendered them acid-fast. It seems, further, that the acid-fast streptothrix form can be converted into a non-acid-fast bacillus by change in the cultural environment. Captain Williams therefore claims that these four types, the acid-fast and the non-acid-fast streptothrix, may be regarded as four different phases of the same micro-organism. His animal experiments, which are not described in detail, afford reason for the belief that inoculation of the acid-fast forms into guinea-pigs can produce nodular lesions at the site of injection as well as in the lymph glands and omentum. The most interesting section of Captain Williams's paper is that which described the results of inoculating leprous patients with a vaccine prepared from both cultures of the acid-fast streptothrix. Without exception the injection was followed by very distinct local and systemic reaction, which was entirely absent after similar inoculations of healthy persons. In some cases, indeed, the local reaction was so pronounced as to be alarming. Treatment of 15 cases was instituted, and the results are so far encouraging that Captain Williams considers it capable of immunising patients against a further spread of the disease, and hopes that it may be possible to effect a cure in early cases by this means. The article is well illustrated by coloured drawings of the various forms of micro-organisms, and the writer has made it clear throughout that his results are not in conflict with those of other recent investigators.

TREATMENT OF SCARLET FEVER AND DIPHTHERIA AT LEICESTER.

THE annual report of the medical officer of health of Leicester (Dr. C. Killick Millard) contains the statement that during the year experiments were made with eucalyptus oil as recommended by Dr. Robert Milne. The details of the treatment as prescribed by Dr. Milne were faithfully adhered to in every particular and no change was made until 100 patients had passed under the treatment. The conclusions Dr. Millard arrives at are that the extent of infectivity was not shortened to anything like the extent claimed by Dr. Milne; indeed, he is not yet satisfied that it has any very appreciable effect in this respect. Nor could he satisfy himself that complications and sequelæ were appreciably diminished, and there was some reason to believe, he thinks, that the number of albuminuria cases were increased. In regard to diphtheria, Dr. Millard says that Leicester has taken a decided stand in the treatment of this disease in hospital entirely without alcohol. It used to be taught that in this disease, owing to the tendency to heart failure, the use of alcohol in large doses was frequently imperative, and that it was orthodox practice to use it. The discovery, however, that the heart failure in diphtheria was due to nerve degeneration, caused by the diphtheria toxin, rendered it improbable that alcohol would be of any real benefit, while the researches of Sims Woodhead, which showed that in horses alcohol definitely interfered with the acquirement of immunity, which is Nature's method of effecting a cure in the case of all zymotic diseases, made it reasonable to regard alcohol as actually contra-indicated. Added to this there is the undoubted fact that alcohol is a drug in which there is a serious danger of a drug habit being established. For these reasons the use of alcohol in the treatment of diphtheria has been entirely discontinued in the Leicester isolation hospital, and was not employed during 1910. Although scarcely more than half the cases of diphtheria notified in the district were removed to hospital this proportion included most of the serious cases, especially those requiring operation. Antitoxin was used in practically all cases. There were 114 cases of diphtheria in Leicester during the year and 11 deaths, and while not suggesting that Leicester's pre-eminently satisfactory position as regards diphtheria mortality is the result of the fact that alcohol was not used, Dr. Millard says it is certainly satisfactory to find that having boldly departed from the orthodox line of treatment the deaths from diphtheria are so few in number. The ordinary death-rate for Leicester is 12·4, and the zymotic death-rate 0·69, both being the lowest on record.

EXTRAPERITONEAL COMPRESSION OF THE COMMON ILIAC ARTERY FOR THE PREVENTION OF HÆMORRHAGE IN DISARTICULATION OF THE HIP.

ONE of the main causes of the heavy mortality after amputation at the hip-joint has always been the great loss of blood which is liable to occur in this operation, and many methods have been devised from time to time to prevent this serious hæmorrhage. One of the most striking of these methods was that brought forward by McBurney in 1894. This consists in digital compression of the common iliac vessels through a small incision made through the abdominal wall. Dr. R. Martin Gil of Malaga has devised a modification of this, which he considers to be an improvement on the original method. He considers that it is undesirable to run the risk of peritonitis through opening the abdominal cavity, and therefore he advocates an extraperitoneal compression of the common iliac vessels. A curved incision is made from 6 to 8 cm. in length, with its concavity forwards passing from a point 2 or 3 cm. from the middle of the iliac crest to the tip of the last rib. When the muscles have been divided the peritoneum is stripped up and it is possible to feel the common iliac artery, and it may be readily compressed. The method deserves a trial, but it does not appear to us that it is materially less dangerous than the original McBurney method.

ONSET OF TYPHOID FEVER BY MENINGEAL SYMPTOMS.

AT a recent meeting of the Société Médicale des Hôpitaux of Paris Professor F. J. Collet and Dr. C. Lesieur of Lyons reported a case of a very rare form of typhoid fever in which the onset was sudden by meningeal symptoms, suggesting cerebro-spinal meningitis. A nurse, aged 29 years, was admitted into hospital on Sept. 30th, 1910. She suddenly became ill on Sept. 27th, with pains in the head, neck, spine, and abdomen, rigidity of the neck, and loss of strength, so that she could not work. She was constipated; the bowels did not act from Sept. 25th to 30th. For three days before admission she had no appetite, could not take any food, and had several attacks of bilious vomiting. On the 29th the evening temperature was 103·2° F. On admission she complained only of pains in the head so severe as to prevent her from sleeping. The face was a little grimacing, especially when she spoke, and the eyes were slightly congested. Movements of the head were impeded by rigidity of the neck, and pressure on the spines of the cervical and dorsal vertebræ was a little painful. The spleen was not felt. The pulse was 100 and good, and the temperature in the morning was 103·1° and in the evening 103·4°. Vomiting occurred again. On drawing the finger over the abdomen marked dermographia, lasting several minutes, was produced. On Oct. 3rd there was incontinence of urine, and vomiting occurred without nausea; the pulse was 120, and the evening temperature 104·2°. Kernig's sign was present in slight degree. Lumbar puncture yielded fluid of normal appearance which on centrifugalisation showed only a few mononuclear leucocytes. On Oct. 4th the pain in the head was much

less and there was no longer any stiffness of the neck. On Oct. 5th there were slight meteorism and two or three rose spots on the abdominal wall, gurgling was produced by pressure on the right iliac region, and the spleen was palpable. The Widal and diazo reactions were positive. On the 6th the meningeal symptoms had entirely disappeared. After this the disease ran the ordinary course of typhoid fever and the patient was discharged cured on Nov. 21st. Thus during the first week the symptoms were markedly those of cerebro-spinal meningitis, but the want of correspondence between the pulse and temperature should have raised suspicion of the true nature of the affection. The negative result of lumbar puncture with the other symptoms established the diagnosis.

Professor Paul Uhlenhuth, M.D., director of bacteriology in the Imperial Health Institute, Berlin, will deliver the Harben Lectures for 1911, before the Royal Institute of Public Health, on Monday, Tuesday, and Wednesday, July 17th, 18th, and 19th, at 6 P.M., in the lecture room of the Institute, 37, Russell-square, London, W.C. Lecture I. will deal with Experimental Studies on Syphilis; Lecture II. with the Biological Differentiation of Proteids by the Precipitin Reaction, with Especial Reference to the Forensic Examination of Blood and Meat; and Lecture III. with Experimental Investigations on Hog Cholera. All interested are invited to attend.

IN spite of very grave difficulties a British Section has been equipped at the International Hygiene Exhibition at Dresden, and was formally opened on June 29th. The British committee is to be congratulated on the success which has attended its persistent efforts to secure proper representation of this country at this important Exhibition.

A SCHOOL OUTBREAK OF ENTERIC FEVER.

BY R. W. C. PIERCE, M.D., B.SC. LOND.,
MEDICAL OFFICER OF HEALTH OF WOKING, ETC.

THE following outbreak is interesting and somewhat uncommon, as the spread of the infection was apparently due, not to contamination of any article of food, but to the presence of an ambulatory or possibly a carrier case at school.

Briefly the history is as follows. The head teacher of a small infants' school had to relinquish work on Feb. 17th, 1911, and was subsequently medically attended at home during some weeks for bronchial catarrh. The school was closed from Feb. 20th. The assistant teacher, who takes the second class—both classes being in the same room—became ill on Feb. 20th and was admitted to the isolation hospital with well-marked signs of enteric fever on March 2nd. Within the next three days five other cases were admitted, three of them with attacks dating from between Feb. 18th and 20th, and the two others with attacks commencing about Feb. 26th. Three of the six cases had relapses after admission. Some of the particulars are tabulated below.

—	Sex and age.	Class attended	Date of onset.	Temperature became normal.	Duration of relapse.
E.W.	F., 23 (teacher).	Class 2.	Feb. 18th–19th	33rd day.	35th to 49th day.
S.L.	M., 7.	,, 1	Feb. 20th.	21st ,,	24th ,, 37th ,,
W.H.	M., 7.	,, 1.	,, ,,	,, ,,	—
F.S.	F., 33.	Mother of child in Class 1.	,, 19th.	27th ,,	—
W.E.	M., 4.	None.	Feb. 25th–26th.	17th ,,	21st to 32nd day.
E.D.	F., 6.	Class 2.	? Feb. 26th.	18th ,,	—

Characteristic spots were present in each case in the primary attacks and second crops in those who had a relapse. Complete clumping of typhoid bacilli was given by the serum in each case in a dilution of 1 in 50 within half an hour.

It will be seen that three of the cases were connected with Class 1 of the infants' school. The infection of W. E, who did not attend school, and also of E. D.—they being next-door neighbours—is probably to be accounted for by contact with K. D., a sister of E. D., K. D. attending Class 1. The last-named child was absent from school on Feb. 10th, 13th, 15th, and 16th, with headache and giddiness. A specimen of her blood tested for Widal's reaction on March 8th gave fairly complete clumping in half an hour in a dilution of 1 in 50. This child, who had probably suffered from a mild attack of enteric, proved to be the earliest suspicious case that could be traced in connexion with the outbreak, except for three cases of jaundice, which is sometimes associated with enteric fever, amongst the school children.

The school department in question was held in a part of another infants' school owing to their own school premises undergoing reconstruction, and the children were conveyed to and from the temporary school in two vans, respecting the overcrowding of which many complaints were made. As two of the children never rode in these vans, they may be excluded as having no connexion with the outbreak. The school drinking supply, cloak-rooms, lavatories, and closets were also utilised by the children of the other infants' department, who were located in the same building, but these were free from suspicion of having caused the outbreak, because none of the children attending this department were affected. As there was nothing in common between the cases in the matter of food-supply or proximity of dwellings (except the two cases, W. E. and E. D.) the probable sources of infection became narrowed down to the class-room.

Attention was then paid to the articles used in common by the children, such as modelling clay, sticks and cubes, pencils, paint brushes, chalk, felt rubbers, &c. It was found that an object-lesson was given on Feb. 8th and again on the 10th with a lemon and an orange which were cut up and distributed among the children, and that a batch of modelling clay was distributed to Class 1 on Feb. 10th, the assistant teacher taking part on all three occasions. The modelling clay, which was kept in a closed tin, was specially suspected owing to the constant manipulation involved in its use and was taken away for examination on March 6th. Washings from the clay rolls were planted in broth and taurocholate broth and plates made on gelatin, agar, and Drigalski medium from the resulting 24 hours' growth. The plain broth cultures gave a mixed growth in which motile organisms resembling in their appearance and movement those of the typhoid bacillus were present, but with the facilities at hand it was not found possible to isolate them. As an interval of three weeks had already elapsed since the infection had taken place the typhoid bacilli even if present at first may not have survived, although the organic matter on the clay and the exclusion of light and air would tend to make this possible.

It seems probable that the infection was introduced into the class-room by one of the children, either by soiling of the floor (and consequently of the dust of the room) by infected excreta, directly or through wetting of the boots in infected urine, or more probably by the contamination of some article such as the plastic clay, by a child suffering from a mild attack of typhoid fever, who resumed the school work with unwashed hands after visiting the water-closet. The latter supposition appears to be the more feasible, as gross contamination of the hands must have taken place if the infection of the mother of one of the children is to be connected with the school. The possibility that the last-mentioned child was a typhoid carrier was considered, but there had been no history of illness, and a specimen of the urine examined in March failed to show any typhoid bacilli. The child's father had an attack of enteric fever 17 years previously, and the father of E. D. had an attack during the South African War.

The class-room was re-opened on March 13th after thorough disinfection and destruction of all inexpensive articles, and no further cases have since been reported either from that school or from the two infected classes who resumed the tenancy of their own school on March 20th. The precaution was taken on reassembling of insisting on each child washing its hands after using the water-closet before

re-entering the class-room. It would, of course, have been more satisfactory to have found the exact source of the outbreak, but in view of the fact that it had evidently ceased to act as such the search was not prosecuted further.

THE NATIONAL INSURANCE BILL.

GENERAL and acute interest continues to be taken in the National Insurance Bill. As is set out in another column, the London County Council is viewing seriously the situation that may be created by interposing Local Health Committees between the Council and the central authority for public health, a matter which has already been brought to the notice of the Chancellor by the Association of Municipal Corporations. From Ireland and Scotland we chronicle additional evidence of the general feeling aroused by the absence from the Bill of any wage limit for medical beneficiaries, a point upon which, however, the Chancellor appears to be inflexible.

HOSPITAL REPRESENTATIVES AND THE BILL.

On Tuesday, June 27th, Sir William Cobbett presided at a meeting of representatives of the voluntary hospitals of Lancashire and Cheshire, held in the Manchester Town-hall. The meeting was called as a sequel to meetings of Hospital Representatives held in London in June at St. George's Hospital and St. Thomas's Hospital, and resulted in the adoption unanimously of a memorial shortly to be presented to the Chancellor of the Exchequer on behalf of the voluntary hospitals of Great Britain and Ireland. The memorial sets out that the voluntary hospitals must supply as heretofore accommodation for persons who will now be insured under the Bill, and who are suffering from serious conditions or require operative treatment; that their funds are derived from public subscriptions, and that they are the centres of medical education and research; that the Bill contains no provision to increase their resources, while in its present state it will reduce their subscriptions; and that the benefits to be conferred by the Bill should be extended to cover treatment in hospitals, which should be able to recoup themselves for expenses incurred in the treatment of insured persons.

THE DISPENSARIES AND THE BILL.

A CONFERENCE of representatives of dispensaries in London and the provinces was held on June 28th. Letters were read from dispensaries in many parts of the country. The feeling was unanimous that the National Insurance Bill as it stood would be most prejudicial to dispensaries whether they were provident or free, and in many cases would practically destroy them. It was pointed out that in some towns as many as a third or more of the population were members of provident dispensaries. A committee was appointed to communicate with dispensaries throughout the country with a view to their concerting measures for submitting their case to the Chancellor of the Exchequer. The following resolution was passed unanimously:—

That in the interest of many hundred thousands of the working classes who receive medical aid from dispensaries all over the country it is most desirable that these institutions, many of which have existed for very many years and are approved by the medical profession, should be utilised for the administration of medical benefits under a national insurance scheme.

THE CHARITY ORGANISATION SOCIETY AND THE BILL.

The following resolution has been adopted by the Council of the London Charity Organisation Society:—

That in view of the extremely complicated nature of the National Insurance Bill, the immense importance of the interests involved in it, and the fact that it seeks to introduce principles and methods entirely novel in the administration of this country, the results of which it is not easy to forecast, but which may in the gravest manner affect the well-being, character, and independence of the wage-earning classes, it is, in the opinion of the council of the Charity Organisation Society, indispensable that the measure should not be pressed forward until such ample time has been given to inquiry and discussion as cannot possibly be secured in the present session of Parliament.

THE TRADE UNIONS AND THE MEDICAL POSITION UNDER THE BILL.

The following resolution, having reference to the National Insurance Scheme, has been forwarded to the Prime Minister and the Chancellor of the Exchequer by the Management Committee of the General Federation of Trade Unions:—

This Management Committee of the General Federation of Trade Unions views with regret the attempts of the medical profession to exploit the National Insurance Scheme, and it is of opinion that the terms for medical treatment as offered by the Bill and explained by the Chancellor of the Exchequer are generous in comparison with those which medical men have been quite ready to accept in the past. The Management Committee is also of opinion that the proposed contributions from workmen, employers, and the State will be quite inadequate to meet the expenditure of friendly benefits if the demands of the Medical Council are acceded to.

What is the Medical Council to which the General Federation of Trade Unions makes reference?

THE IMPERIAL MEDICAL REFORM UNION AND THE BILL.

The following appeal from the central committee of the Imperial Medical Reform Union has been sent to all Members of the House of Commons:—

GENTLEMEN,—In view of the serious injury to medical men in general practice that must inevitably result from the National Insurance Bill in its present form, should it become law, we venture most earnestly to appeal to you in justice to a profession which has done so much for humanity to propose and support such amendments to the Bill during its passage through the committee stage as will render it more acceptable to medical practitioners generally. Whilst agreeing in the main with the amendments suggested by the General Medical Council and the British Medical Association, we are convinced that they do not go sufficiently far to safeguard the interests of the profession.

Firstly: The wage limit for "employed contributors" has been placed much too high, and we are of opinion from our experience of the working classes that no person whose *income from all sources exceeds thirty shillings a week* should be entitled to claim "medical benefit [Sec. 8 (a)].

Secondly: We suggest that medical officers under the scheme should be paid for actual services rendered and not by capitation allowance. This method of payment has been carried out for many years past by the National Deposit Friendly Society with satisfaction to the members and to the doctors. During the year 1910 this society paid in fees to doctors the sum of £35,251 6*s.* 9*d.*, an average of 3*s.* 2½*d.* for each member of the society. Provision should also be made for payment for operations, long distance visits, and other extra services.

Thirdly: In the interests of the patient as well as of the doctor we urge that the latter should be entitled to supply the necessary medicines.

Fourthly: We submit that doctors should not be expected to attend under the Act patients suffering from venereal diseases or illnesses, such as delirium tremens, directly arising from the excessive use of alcohol, or due to other acts of misconduct.

In conclusion we respectfully submit that if the above suggestions are embodied in the Bill the measure will be decidedly more satisfactory to the public and the whole profession. As this is not a party question and as our suggested amendments in no way infringe any vital principle of the Bill we confidently trust to receive an assurance that you will give them your support.—We are, Gentlemen, yours faithfully,

ROBERT BELL, Chairman.
GEORGE BROWN, JNO. POLLOCK SIMPSON } Hon. Secretaries.

Imperial Medical Reform Union, 17 and 18, Basinghall-street, London, E.C., June 29th, 1911.

THE NATIONAL INSURANCE BILL IN RELATION TO PUBLIC HEALTH ADMINISTRATION IN LONDON.

Report of Parliamentary Committee.

THE London County Council on July 4th received a report from its Parliamentary Committee on behalf of the various committees affected, with regard to the provisions of the National Insurance Bill from a local government point of view.

The report criticised the interposition of an independent authority, such as the proposed Local Health Committee, between the Council and the central authority for public health. The Public Health Committee in particular considered that it was inadvisable to set up a new authority having public health powers in the County of London, and that the duties of the new committee should be performed by the Council, representation being given to approved societies and deposit contributors. The Parliamentary Committee, however, could not support this suggestion, noting the Chancellor's statement to the deputation from the Association of Municipal Corporations that it would be "impossible." Criticising the composition of the Local Health Committees, the report stated that the representation proposed to be given to the Council, consisting of less than one-third, would place upon the Council some responsibility for the committee's administration, though it would be insufficient to give the Council an effective voice. While the representation of the Council on the Local Health Committee might be adequate as regards the administration of the Post Office fund, it was clearly inadequate for the

purpose of the duties in connexion with medical and sanatorium benefits and other public health duties with which the Local Health Committee would be charged. The position of this proposed independent county authority in the scheme of local government was anomalous. It would have powers and duties which either properly belonged to local government authorities or could be conveniently and efficiently performed by them. Its funds, so far as it could have any funds other than those derived from the Insurance Fund, must be obtained from the county ratepayers, whose representatives would be in a minority on the Local Health Committee. The Local Health Committee would depend to some extent upon contributions made by the bodies whose actions in matters of public health it would criticise and stimulate. On these grounds the new committee appeared to be an unsuitable body for the purpose it was intended to serve; the setting up of such an authority would cause overlapping of jurisdiction and duplication of administrative machinery; and if any additional public health powers of the kind in question were required in London they should be entrusted to the County Council. With regard to the provision of sanatoriums, the report observed that the matter was apparently left by the Bill optional to the Council, but it might be anticipated that public opinion would virtually compel the exercise of the powers. The provision in the Bill for the recovery of expenses from a local authority in default added a new complication to an already complicated system of local taxation. The clause stating that the medical officer of health of the county, at the request of the Local Health Committee, might attend meetings of the committee might lead to difficulties of administration.

The Bill in Relation to School Medical Work.

The Council's work in relation to the medical treatment of school children could not but be profoundly though indirectly affected by the Bill, which would entirely revolutionise the conditions of medical treatment and relief existing amongst the whole of the elementary school population. The wage-earning classes would be brought universally into relation with medical practitioners, and the present haphazard methods would be superseded by a definite organisation. The hospital system must be affected. Voluntary funds dependent on workers and employers, like the Hospital Saturday Fund, might disappear. The need of charitable relief for the working population, which was the *raison d'être* of the hospitals at present, would no longer exist. The hospital out-patient departments, so far as adults are concerned, will largely disappear, just as in-patient institutions and hospitals must come eventually under the supervision or control of the Local Health Committees. Under these conditions, on the one hand the out-patient departments would be freed to undertake the work of medical relief of school children; and, on the other hand very serious objections to subsidising charitable institutions which were under no official supervision or control would vanish. The disappearing (voluntary) funds would practically throw much of such hospital provision open to new arrangements and make support from public funds necessary. Under the Bill Local Health Committees were to have considerable powers of subsidising institutions for medical treatment, and under Clause 47 the erection of such institutions by local authorities was foreshadowed. For many purposes clinics must be established locally to deal with special branches of medical relief. As such fundamental changes would take place inevitably under the Bill in the organisation of medical relief amongst the working classes, the Council's position in regard to the treatment of school children could not fail to be seriously affected. To secure unity, economy, and efficiency, it would almost be necessary eventually for the Council to link up its organisation with that of the Local Health Committees, and conjointly with them to arrange for the establishment or subsidy of institutions for medical relief, the Local Health Committees being responsible for that share of the cost which would be expended in the medical relief of workers under the Insurance Scheme, and the Council for that share expended in the medical relief of school children. It seemed, therefore, that the Council would be well advised in avoiding any permanent commitments, and in looking upon all present schemes for medical treatment as provisional until the great reorganisation of the medical relief of the working classes foreshadowed in the Bill had been carried into effect.

The Financial Aspect of the Bill.

The Finance Committee, reporting upon the Bill in its financial aspects, urged that the Council should not be in the position of being forced to make up deficiencies incurred by a Local Health Committee without having some control over the operations that had led up to a deficiency. The clause which imposed a serious potential liability upon the Council and local authorities in the event of excessive sickness due to bad housing or insanitary conditions, even if workable, was inapplicable to London. The ratepayers of the county as a whole might be heavily penalised as a result of the default of a borough council, and the County Council might be involved in large expenditure on account of epidemics which it had no power to prevent. As to the provision that the Treasury and the County Council should each make good one-half of any "reasonable and proper" deficiency resulting from the work of the Local Health Committee, the Finance Committee noted that the Chancellor said to the deputation from the Association of Municipal Corporations that "Local Health Committees had no right to hypothecate either rates or taxes for the purpose of expenditure without the full and unfettered consent of the County Council and the Treasury," but this declaration did not appear to be consistent with the assurance to the medical profession in the Chancellor's speech to the British Medical Association on June 1st. On that occasion he suggested very specifically that the Local Health Committees had behind them the rates and taxes in case their funds for medical benefit were insufficient. It appeared to the Finance Committee to be very doubtful whether, in actual practice, the local authorities would have any real discretion in the matter under the Bill as it now stood. The position would resolve itself largely into making good a deficiency brought about by past action unless the local authorities were consulted at an earlier stage.

The Parliamentary Committee, though unable to adopt the suggestion of the Public Health Committee that the powers and duties of the new committee should be conferred on the Council, advised that amendments in the National Insurance Bill be sought to provide that:

1. The Council shall not be liable to make good out of the county fund one-half of any sums expended on medical benefits in excess of the amount received from the Insurance Fund by the Local Health Committee.
2. The Council shall not be liable to provide or maintain sanatoria.
3. Complaint of default by a local sanitary authority shall be made (in London) in the first instance to the County Council, which shall make any necessary order, the Local Government Board being appealed to only on default of the County Council.

The report was only reached towards the end of a long sitting, and detailed consideration of the proposed amendments to the Bill was adjourned until next week.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the office, 37, Soho-square, London, on Friday, June 30th, Sir HENRY MORRIS, the treasurer, being in the chair. Among those who attended were Mr. J. Paul Bush, Dr. Charles Caldecott, Dr. Charles W. Chapman, Sir William S. Church, Mr. Andrew Clark, Dr. W. Collier, Sir Dyce Duckworth, Dr. Arthur Grayling, Dr. F. de Havilland Hall, Mr. Horace E. Haynes, Mr. J. B. Lawford, Mr. J. H. Morgan, Sir Shirley F. Murphy, Dr. F. Needham, Sir R. Douglas Powell, Dr. Guthrie Rankin, Dr. St. Clair B. Shadwell, Surgeon-General Sir Lionel D. Spencer, Dr. Frederick Taylor, Dr. Herbert Taylor, and Dr. J. Roberts Thomson.

The SECRETARY read the list of successful candidates for pensionerships and foundation scholarships as follows:—

PENSIONERSHIPS.	Votes.
1. Agnes Paterson	7827
2. Hermine Armstrong	5778

FOUNDATION SCHOLARSHIPS.	
1. Hugh E. Cutfield	8286
2. Alec F. Watson	7973
3. Colin P. Ledward	7555
4. Francis R. M. Buckell	7446
5. Charles E. Carruthers	5822
6. Thomas H. W. Procter	5644

The SECRETARY stated that Robert E. P. Shearer and A. W. Glover Moore would be appointed foundation scholars, under By-law 24, at the Council meeting which would be held immediately after that meeting.

In moving the adoption of the report for the past year the CHAIRMAN referred to the loss which the College had sustained in the death of Sir Constantine Holman, who for over 30 years as an active member of the Council, and for 19 years of that period as treasurer, had so ably promoted the interests of the College by his energy and wisdom. Although there already existed at the College a memorial of his labours in the Holman Reading-room, the Council was about to place a suitable tablet in the College chapel as a mark of its appreciation of his conspicuous efforts on behalf of the institution. After referring briefly to the salient points dealt with in the report the Chairman drew attention to the decision recently arrived at by the General Medical Council in regard to the recognition of approved secondary schools as institutions in which medical study may be commenced, and mentioned that several members of the General Medical Council paid a visit to the College a few weeks ago and had expressed their gratification at inspecting the well-equipped laboratories for the teaching of science. He said that at the last meeting of the General Medical Council one of these members expressed the opinion that Epsom College ought to be recognised as an institution in which medical study may be commenced, as it was impossible to go round that school without recognising that the whole system of scientific teaching there was of a higher order than that found in the average medical school. At the same meeting another member of the General Medical Council who had visited Epsom College expressed the opinion that the school ought to be on the list of approved institutions in which medical study may be commenced, and stated that he was perfectly willing to propose a motion to that effect.

The report of the Council to the governors stated that in spite of the demands which constantly are being made upon the purses of all classes the receipts from annual subscriptions again showed an increase, this satisfactory feature being in a great measure due to the zealous efforts of honorary local secretaries and other friends of the College. Whilst expressing the cordial thanks of the governors to all who had rendered assistance, the Council earnestly asked for a continuation of their help in view of the fact that a sum of close upon £5000 must be obtained by means of annual contributions in order that the full number of 50 pensionerships and 50 foundation scholarships might be maintained. There were at the present time on the books of the College 49 ordinary pensioners, 8 Pugh pensioners, 10 France pensioners, 14 Da Silva pensioners, 3 Morgan annuitants, 5 Highett pensioners, of whom two receive £30 and three receive £10 a year, 1 R. R. Cheyne annuitant, and 4 Brodie Sewell pensioners. The election that day would bring the number of ordinary pensioners up to 50. The governors would be glad to learn that under the will of the late Mrs. Mary Helen Christie, of Ribsden, Windlesham, Surrey, who died in February last, a legacy of £3200 had been bequeathed to the College to provide two pensions of at least £40 each for medical men. The Council also had pleasure in reporting the receipt of a donation of £50 from Miss Esther Du Bois, the interest thereon to be spent in prizes for boys on the Foundation, in memory of Anne Du Bois. The general work and the discipline of the school had been satisfactory, the various games having been played with the usual enthusiasm, and the school institutions being in a flourishing condition. The study of aeroplanes and the problems of flight had proved to be very popular with the boys. A team again went to Bisley to shoot for the Ashburton Shield and took the thirty-ninth place out of 55 schools. There was an unmistakeable improvement in the shooting and the Officers' Training Corps was doing excellent work.

The report further stated that since the last annual general meeting of the governors the Council had inquired very carefully and exhaustively into the administration of the College infirmary, as well as into the questions of sleep, dress, dietary, and medical inspection of the boys, in order that the governors might rest assured that such matters would be brought into line with modern requirements. An inspection of the whole school was held in June, 1910, under the auspices of the Oxford and Cambridge Schools Examination Board, and the report received by the Council was most satisfactory. The examiners also commented on the efficiency of the masters, and on the fact that they so conducted their classes as to attract the intelligent interest and attention of the boys in their work. Since the last annual general meeting six boys had passed the whole or a part of the first examination for medical degrees of the University of London, 14 boys had passed the matriculation examination of the same University, 9 boys had gained the higher certificate of the Oxford and Cambridge Schools Examination Board, and 25 had gained the lower certificate. Last year the Du Pasquier scholarship was awarded to C. W. S. Davies-Jones, the Stone scholarship was given to W. F. Marshall, and the Jenks Memorial scholarship was awarded by the Royal College of Surgeons of England to G. Gibbons. The hospital scholarships were awarded as follows: St. Bartholomew's, M. S. Beaumont; London, J. N. Deacon; Middlesex, H. Wearne; St. Mary's, R. M. Handfield-Jones; St. Thomas's, G. M. Kendall; and University College, together with the Carr exhibition, which goes with it, H. Ll. G. Hughes.

The report having been adopted, the usual formal business was transacted, after which a cordial vote of thanks to the chairman for his indefatigable labours as treasurer was proposed by Sir WILLIAM CHURCH, and was carried with acclamation.

MEDICINE IN SCANDINAVIA.

No. II.—DENMARK.[1]

Number of Medical Men and their Incomes.

DENMARK, with a population of 2½ millions, has about 1800 medical practitioners, who are, therefore, in the ratio of 1 to 1400 inhabitants. The population is fairly dense, for the area of the country is only 14,553 square miles; but the medical man's lot is not altogether a happy one, for both the cost of living and competition have much increased lately, whereas his fees have remained the same. Medical earnings in some cases do not exceed from 3000 to 4000 kroner (£166 to £222), and incomes ranging from 40,000 to 50,000 kroner (£2220 to £2777) are only made by a few popular specialists. In the period 1908-09 there were 502 medical men in Copenhagen who paid taxes. The income (from all sources) of 220 of these men was rated at less than £277 each. In 1907 the average income for medical men in Copenhagen from the age of 25 to 30 was £98; from 30 to 40, £211; from 50 to 60, £624; and from the age of 60 and over it was £603. These sums represent interest on capital as well as earned incomes, but the average amount of the latter far exceeds that of the former.

Medical Education.—Government Appointments.

Medical degrees are given only by the University in Copenhagen, where the student takes about seven years to qualify. Two examinations are held: Part I. includes anatomy, physiology, chemistry, and physics; Part II. includes medicine, surgery, and midwifery, and it must be taken not more than six years after Part I. Clinical appointments are held at the hospital before Part II. is taken, and after qualification resident hospital appointments may be held for a year. There are no special diplomas corresponding to the F.R.C.S. or D.P.H., but the medical man desirous of specialising in any particular branch of the profession attends at the special hospital department he may choose and holds its appointments. He may also take the degree of M.D., the original contributions to which may be purely surgical.

There are about 100 Government district medical officers in the country, which is divided into 12 areas. Each area is managed by a senior medical officer, who in his turn is under the control of a central "Sundhedsstyrelse" or Sanitary Board, the establishment of which in its present form dates from 1909. For the larger towns there are special medical officers. The system of Government medical officers has been found faulty to such an extent that its reorganisation has been placed in the hands of a special medical commission whose findings have not yet been published.

Organisation of the Medical Profession.

The Danish Medical Association (Den Almindelige Danske Laegeforening) was founded in 1857 by 80 medical men to protect the interests of the profession. In 1910 its membership had risen to about 1600, and its sphere of influence had

[1] No. I. was published in THE LANCET of July 1st, 1911, p. 36.

increased proportionately. One of its most important functions in recent years has been the supervision of contract medical practice, which has assumed enormous proportions. The number of sickness and accident societies recognised by the Government in 1907 was 379, with a total membership of 473,694. The conflicts which have inevitably arisen between these societies and their medical officers have repeatedly proved the value of the Association to its members.

The Association's campaign against quackery and secret remedies has been active and sustained, but its efforts have hitherto been largely ineffectual. Homœopaths and others whose medical practice is not based on scientific principles are excluded from the Association's membership. Although the branches of the Association are subordinate to the central organisation they are allowed considerable latitude in the framing of their own rules, and such restrictions as those with regard to advertising outside the medical press vary considerably in different localities. Disputes of a professional nature arising between members are settled by arbitration, and the refusal to abide by the decision of the arbitrators is punished by loss of membership. Loss of membership (but not of the right to practise) is also incurred if the Association finds a member guilty of unprofessional conduct, or if the executive of a branch of the Association at the request of half its members or if the executive of the Association advocates dismissal of a member, provided that the proposal is supported by a majority of the votes given in writing by the members of the local branch. The disciplinary powers of the Association have also been effectually applied to the price-cutting tactics of insurance companies and other bodies, and members must now charge for their services according to the Association's tariff. Members are also forbidden to issue certificates to insurance companies for a fixed yearly salary. The Association has, moreover, laid down definite rules for the conduct of its members in their mutual relations.

The Association has materially influenced the framing of recent sanitary laws, notably those relating to tuberculosis and prostitution. As an example of the anomalies which meet the medical practitioner in Denmark, and which require the vigorous action of the Association, may be mentioned the unrevoked law of 1825, according to which the district medical officer is bound to treat venereal disease at the rate of 4 kroner per patient, the fee being paid only if the treatment is successful. In practice, however, this law is commonly evaded. Another anomaly the formal removal of which the Association has secured is the surgical part played by barbers, who were eligible to practise surgical first aid in Copenhagen until the end of the last century.

Sanatoriums.—Scientific Contributions.—Medical Literature.

The campaign against tuberculosis has been conducted largely on sanatorium lines, and the number of sanatoriums, public and private, now in existence actually exceeds the demand.

Danish contributions to the science of medicine include those of W. Meyer (adenoids), B. Bang (tuberculosis), J. Petersen (history of medicine), C. Gram (bacteriology and medicine), H. Howitz (gynæcology), C. Rovsing (surgery), C. J. Salomonsen and T. Madsen (bacteriology), G. Dreyer (professor of pathology at Oxford), C. Bohr and V. Henriques (physiology), J. C. Bock (pharmacology), K. Faber (medicine), M. Tscherning (physiological optics), E. Ehlers (leprosy), H. Mygind and E. Schmiegelow (oto-laryngology), S. Saxtorph (surgery), and C. O. Jensen (cancer). The late Dr. Finsen's works on light as a therapeutic agent are known to all, and much original work of a similar character is still being carried on in Denmark.

The medical literature of the country has reached a high scientific standard. The senior journal is *Ugeskrift for Laeger*, the official organ of the Association. The weekly journal, *Hospitalstidende*, edited by Professor Rovsing, usually contains excellent original papers and reviews of recent medical literature. Other journals are *Dansk Klinik*, *Nordisk Tidsskrift for Therapi*, which is a monthly journal, and *Bibliotek for Laeger*, which appears every other month. The majority of text-books in use are German. English and French works are less known, but most Danish medical men read all three languages.

The author wishes to thank Dr. Christopherson, the secretary of the Medical Association, for valuable assistance in providing much of the material for this paper.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are among the amounts received at the Mansion House up to June 30th (total, about £17,500) :—

	£	s.	d.
St. Paul's Cathedral	336	0	0

MEDICINE AND THE LAW.

Murder Committed by a Person under the Influence of Mental Distress.

AT the Old Bailey recently a very painful trial resulted in the conviction of a flower-seller, Margaret Murphy, 38 years of age, for the murder of her seven months old child. Murphy was the mother of six children, three of whom were dependent upon her, as she lived apart from her husband. She was unable to pay her rent, and having gone to Epsom to sell flowers and lost the whole of her money there, after her return, according to her statement, she remained awake all night through worry. In the morning she obtained some spirits of salts, some of which she gave to her baby, causing its death, and herself took the rest, but, although she was found unconscious, she recovered. Evidence was given by Dr. W. C. Sullivan, medical officer at Holloway Prison, to the effect that having had the prisoner under his observation for nearly a week he was of the opinion that she did not fully know what she was doing when she administered poison to the child. She had told him that she was anxious about her rent and afraid that she would be sent to prison, and he considered her to be emotionally unbalanced when she committed the act, but could not say that there was any mental disease discoverable, or that at the time of the alleged murder she was insane. Mr. Justice Darling in summing up dwelt upon the painful nature of the case, but asked the jury to remember that they had a duty to perform, and intimated to them his opinion that the occasion was rather one for the exercise of the clemency of the Crown upon the advice of the Home Secretary than for a verdict of insanity. A verdict of "Guilty" was returned, coupled with a strong recommendation to mercy, and sentence of death was passed in the usual form. The death sentence will not be carried out, and the case is one of those which show the difficulty of distinguishing the varying degrees of mental disturbance which may qualify the guilt of a person charged with "Wilful murder." It is also a case likely to strengthen the hands of those who are seeking to introduce such changes in the procedure relating to trials for this crime as will prevent the solemn death sentence being pronounced when it is extremely unlikely that it will be carried out.

Keeping a Lunatic in an Unlicensed House.

At the Old Bailey recently Jane Mathieson, keeping a boarding-house in Penywern-road, London, was indicted for taking charge of a lunatic for payment in an unlicensed house, and also for unlawfully neglecting and ill-treating her. The lunatic in question was an elderly lady named Blackley, who was found to have purchased annuities amounting to £260 a year, and to have afterwards assigned the whole of this income to the prisoner, in whose house she had for some time resided on the terms that she should be provided in return with board and residence. A lady, who had been employed by the prisoner as a manageress, had had her attention attracted by cries proceeding from the basement and had been told by the prisoner that it was occupied by "a rich old lady who is worth more to me than all the other boarders." The manageress called the attention of the police to the matter, including the manner in which the old lady in question was apparently being fed, and inquiries followed, with the result that Miss Blackley, who was discovered in the basement ill-clad and neglected, was certified as insane and removed to an asylum, summonses being issued against the proprietress of the house. Mathieson pleaded guilty to the first count of the indictment, for unlawfully taking charge in an unlicensed house, and was ordered to pay a fine of £50 and to be imprisoned until the money should be paid. It is desirable that all possible publicity should be given to a case of this kind, as although such incidents may not be common, they occur from time to time. A great deal of unnecessary suffering is endured by the victims, and, as a rule, discovery can only take place through the intervention of some outside person who has to assume the responsibility of interfering. It is well that all should know that the police will interest themselves in such a case, and by taking the necessary steps to inquire into it can secure proper treatment for the afflicted person with punishment for those who have taken advantage of the helpless.

The Proposed Weir Hospital at Streatham.

The Charity Commissioners are about to seal an order establishing their revised scheme for giving effect to the will of Benjamin Weir which was proved in the Principal Registry of the Court of Probate on April 24th, 1902, for the provision of a hospital and dispensary at Streatham. It will be remembered that the original scheme of the Commissioners, disallowed by the Law Courts at the instance of the Wandsworth Borough Council, proposed to hand over the bulk of the Weir bequest to the Bolingbroke Hospital, Battersea. The new scheme provides, *inter alia*, that "the trustees of the charity shall establish on the site of the messuage and tenement known as The Hawthorns, a Cottage Hospital for the benefit of the inhabitants of the parish of Streatham and the neighbourhood, with such a number of beds and such accommodation for the staff, appliances, equipment, offices, and conveniences suitable for the administration of the hospital or the affairs of the charity as having regard to the funds applicable to, or available for, the purposes of the charity, the trustees may think proper. The staff of the hospital shall consist of such resident and other medical officer or officers, matron, dispenser, nurses, servants, and attendants as the trustees may from time to time consider necessary. The hospital shall comprise an out-patient department, with or without a dispensary. For the purpose aforesaid, the trustees may either adapt the existing buildings on the said site, or pull down and erect on the said site and on any site acquired as hereinafter mentioned new buildings in accordance with plans to be approved by the Charity Commissioners. They may also, with the approval of the said Commissioners, acquire by purchase any land and hereditaments contiguous to the said premises known as The Hawthorns which may be required for the enlargement of the said site, so as to render it convenient for the objects of the charity. The trustees shall use the messuage and tenement known as No. 22, Old Devonshire-road, either as a dispensary or otherwise as an adjunct to and as part of the hospital until they shall, with the approval of the Commissioners, otherwise determine. Subject to the provisions of the said will and of this scheme, the hospital shall be administered by a committee of management, constituted as directed by the said will, in accordance with rules to be made from time to time by them." The property of the charity, as shown by a schedule, comprises, besides the two houses known as The Hawthorns (No. 17, Grove-road, Clapham Park) and 22, Old Devonshire-road, Balham, consols and other stocks and shares, &c., of the gross value of about £120,000.

THE MEDICAL EXAMINATION OF DRIVERS OF MECHANICALLY PROPELLED VEHICLES.—The proprietors of mechanically propelled public service vehicles in the metropolis have been notified by the police that in future all applicants for licences to drive public service motor vehicles will have to undergo a medical examination or produce a certificate as to fitness.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Viscount Portman presided on June 30th at a meeting at 22, Portman-square, London, for the inauguration of a ladies' association in connexion with Queen Charlotte's Hospital, Marylebone-road. He explained that the object of the association was to obtain increased support for the hospital and to spread a knowledge of the excellent work in which it had been engaged for nearly 160 years. Most useful work might also be done by a ladies' association in providing linen for the mothers and infants in the hospital. Sir Samuel Scott, M.P., chairman of the committee of management, referred to the increasing difficulty experienced in obtaining subscriptions for hospitals, and hoped that the ladies' association would be instrumental in increasing the income from this source. The committee wanted ladies to come and see the hospital and become interested in the work. Dr. W. J. Gow (senior physician) spoke of the valuable work done by the hospital, and urged the importance of a ladies' association. At other hospitals they had been most useful. A resolution for the formation of a ladies' association was passed. Viscountess Portman was elected president of the association and an executive committee was formed.

Public Health.

THE PUBLIC HEALTH OF GIBRALTAR IN 1910.

THE annual report on the public health of the civil population of Gibraltar for the year 1910 shows that the inhabitants of this colony (other than military) number 18,134, of whom 15,451 form the "fixed civil population"—that is, British subjects; while "resident aliens" number 2683: there has been a decrease of 217 since the numeration at the end of 1909. Under the exceptional conditions prevailing in this fortress such a decrease is satisfactory; it would indeed be more satisfactory if the heading "resident aliens" were to disappear altogether. The birth-rate, 25·2 per 1000 living, is the lowest but one yet recorded; it is practically the same as that for England and Wales (25·6) in 1909, and contrasts strongly with the rate of 36·7 registered in Malta. The general death-rate was 18 per 1000, which was higher than in any year since 1905. The deaths of children under one year were at the rate of 135 per 1000 births, not an excessive figure considering the peculiar conditions of the place, but a disappointing sequel to the very low rate of 73·4 in 1909. Of the total 53 deaths under one year, inflammation of the stomach and bowels accounted for 24, and inflammation of the lungs for 8. The medical officer of health hopes that classes of instruction may be started for the education of mothers in the rearing of infants and the care of the home. Of the infectious diseases notified, tuberculosis (66 cases), whooping-cough (64), and measles (59) were the most prevalent. The measles outbreak was mild in character, only one death resulting; scarlet fever cases numbered 31, but none were fatal; of diphtheria there were 13 cases, scattered in distribution, and with no definite cause to be traced; five of these were fatal. There were 14 cases of small-pox, 4 being contacts, and 3 others evidently infected in Linea. The origin of the remaining cases is considered to have been due to Spanish workpeople coming into Gibraltar when sickening for the disease or convalescent. It is satisfactory to learn that all the cases were adults not vaccinated since infancy, the revaccination ordinance having protected the children and the young population. There were only three cases of Mediterranean fever, though from 10 to 15 per cent. of the goats still yield a reaction with M. melitensis; their milk is therefore dangerous in the raw state. Enteric fever was notified in 25 cases, of which 20 contracted the disease on the Rock; there were 6 deaths; no definite cause is assigned. Tuberculosis appears to be increasing: 66 cases were notified and 28 deaths occurred, compared with 46 cases and 25 deaths in the previous year. The health officer mentions that compulsory notification was introduced in 1906, but that nothing has been done to ameliorate the lot of those suffering from the disease, or to protect those who live in proximity with them from being infected. Several instances are given in which transmission from one member of a family to another appears to have occurred. It is urged that a tuberculosis dispensary be established, where patients can be treated and educated in the measures necessary to safeguard other members of the household from infection; and that cases of the disease be tracked out in connexion with those under treatment; some such scheme, it is hoped, may be brought into operation before long. For more serious cases a sanatorium would be required. A committee has been appointed to inquire into the whole question.

Perhaps the most important matter as regards sanitation in Gibraltar is the extremely close aggregation of the houses, and the fact that the large majority of them are of the tenement order; many of these consist of single rooms. As the health officer very truly says, it is only by the abolition of the most crowded and insanitary areas that much improvement can be effected in certain parts of the town. It is understood that long leases are not now granted; and if Gibraltar is to be regarded as a fortress rather than a colony the correct policy would be not only to retain, but to recover the power over all property in land in order that it may be dealt with at discretion in the higher interests of the community. A case has occurred in the past year where a plot of ground of 5500 sq. ft. has been acquired by the Commissioners, with the help of the Colonial authorities, on which an open space will be formed. The value of Gibraltar consists in its being an impregnable fortress, and a fortress is not impregnable if it is so overcrowded as to be insanitary. Moreover, the water-supply is by no means unlimited; the summer dry weather of 1910 was prolonged into December, such an absence of rain during September, October, and November not having occurred since 1882; fortunately, heavy rains in the previous wet season had left a full storage-supply and condensing was only required for a few days. It is understood that additional storage for 2,000,000 gallons is to be provided, also an extension of the catchment area. Improvements have been made in the sewerage system, some part of the old deep sewer from St. Jago's barracks, through Queen-street and Town Range, having been relaid; during the present year this work of relaying the most defective sewers will, it is hoped, be completed. Refuse is efficiently disposed of in a destructor, and before long it is expected that night-soil from various War Department premises will also be consumed in this way so as to avoid nuisance in Catalan Bay and at the Eastern Beach.

This report by Major C. E. P. Fowler, R.A.M.C., medical officer of health and sanitary officer to the garrison, shows what a careful watch is kept on all the conditions affecting the public health both of the civil and of the military populations; the position is a difficult one to hold and requires considerable tact and administrative ability on the part of its occupant. The excellent results obtained are most satisfactory.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 9211 births and 3623 deaths were registered during the week ending July 1st. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had declined in the 11 preceding weeks from 16·8 to 11·3 per 1000, did not exceed 11·7 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged 13·8 per 1000, and in London during the same period the mean annual death-rate did not exceed 13·2 per 1000. The recorded annual death-rates during last week in the 77 towns ranged from 3·1 in Hornsey, 4·6 in Bournemouth, and 6·9 in Northampton, to 17·6 in Sunderland, 17·7 in Great Yarmouth, and 19·8 in Walsall. The 3623 deaths from all causes in the 77 towns last week showed an increase of 137 upon the low number in the previous week, and included 268 which were referred to the principal epidemic diseases, against 264 and 273 in the two preceding weeks. Of these 268 deaths, 76 resulted from measles, 70 from infantile diarrhœa, 62 from whooping-cough, 35 from diphtheria, 17 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases, which had been equal to 1·2 and 0·9 per 1000 in the two previous weeks, was again last week 0·9. The fatal cases of measles in the 77 towns, which had been 125, 124, and 81 in the three preceding weeks, further declined last week to 76, and were fewer than in any previous week of this year; the highest annual death-rates from this disease recorded in these towns last week were 1·2 in Wigan and in Bolton, and 2·8 in Great Yarmouth. The 70 deaths attributed to infantile diarrhœa in the 77 towns were fewer by 18 than those returned in the previous week; they included 15 in London and its suburban districts, 6 in Birmingham, 13 in Liverpool, and 6 in Manchester and Salford. The fatal cases of whooping-cough, which had been 81, 69, and 63 in the three preceding weeks, further declined to 62 last week, but caused annual rates equal to 1·4 per 1000 in Sunderland and 2·2 in Bootle. The 35 deaths referred to diphtheria exceeded the number in the previous week by 14, and included 11 in London and its suburban districts, 6 in Manchester and Salford, and 2 both in Leeds and in Newport (Mon.). The 17 fatal cases of scarlet fever also showed a slight increase on the number in the previous week; 3 occurred in Birmingham, and 2 each in Bristol, Coventry, and Leeds. The 8 deaths referred to enteric fever corresponded with the low number in each of the two preceding weeks. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased in the 11 preceding

weeks from 982 to 1223, had further risen to 1226 at the end of last week; 163 new cases of this disease were admitted to these hospitals during the week under notice, against 190 and 159 in the two previous weeks. These hospitals also contained 774 cases of diphtheria, 433 of measles, 278 of whooping-cough, and 33 of enteric fever, but not one of small-pox. The 961 deaths from all causes in London showed an increase of 40 on the exceptionally low numbers in the previous week, and included 117 which were referred to diseases of the respiratory system, against 141, 139, and 111 in the three preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had declined from 177 to 136 in the five preceding weeks, rose again to 169 in the week under notice; 335 inquest cases were registered. The causes of 29, or 0·8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 55 other smaller towns; the 29 uncertified causes of death in the 77 towns last week included 10 in Birmingham, 5 in Liverpool, and 2 in Bootle.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, with an estimated population of 1,710,291 persons, 945 births and 467 deaths were registered during the week ending July 1st. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 17·7 to 13·3 per 1000, rose again to 14·2 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged 16·7 per 1000 of the revised estimate of their population, and exceeded by 2·9 the revised mean rate during the same period in the 77 large English towns. The annual death-rate during the week under notice in the eight Scotch towns ranged from 10·2 in Aberdeen and 11·6 in Leith, to 16·0 in Perth and 17·4 in Dundee. The 467 deaths from all causes in the eight towns last week showed an increase of 32 on the low number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 64 and 58 in the two preceding weeks; of these 63 deaths, 22 resulted from whooping-cough, 20 from diarrhœa, 13 from measles, 5 from diphtheria, and 3 from scarlet fever, but not one either from enteric fever or small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·9 per 1000, and exceeded by 1·0 the mean rate from the same diseases in the 77 English towns. The fatal cases of whooping-cough in the eight towns, which had declined in the four preceding weeks from 43 to 25, further declined last week to 22, of which 13 occurred in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The 20 deaths attributed to diarrhœa showed a marked increase upon the numbers in recent weeks, and included 7 in Glasgow and 5 in Dundee; 16 of the 20 deaths from this disease were of infants under two years of age. The 13 fatal cases of measles were fewer by 3 than those returned in the previous week; 11 occurred in Glasgow and 2 in Perth. Of the 5 deaths referred to diphtheria, 3 were returned in Glasgow and 2 in Perth. A fatal case of scarlet fever was registered in Glasgow, Edinburgh, and Greenock. The deaths referred to diseases of the respiratory system in the eight towns, which had been 49 and 51 in the two previous weeks, declined to 48 in the week under notice, and were 7 below the number returned in the corresponding week of last year. Of the 467 deaths from all causes in the eight towns last week, 157, or 34 per cent., were recorded in public institutions, and 8 were attributed to different forms of violence. The causes of 16, or 3·4 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons (based on the recent Census numbers), 836 births and 374 deaths were registered during the week ending July 1st. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 17·1 to 13·5 per 1000, rose again to 17·0 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns averaged 17·9 per 1000; the mean rate during the same period in the 77 English towns did not exceed 13·8 per 1000, and in the eight principal Scotch towns was 16·7 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 19·5 in Dublin (against 11·1 in London), 15·7 in Belfast, 18·4 in Cork, 14·1 in Londonderry, 14·9 in Limerick, and 5·7 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week was equal to 16·3 per 1000. The 374 deaths from all causes in the 22 towns last week showed an increase of 77 upon the low number in the previous week, and included 21 which were referred to the principal epidemic diseases, against 23 and 27 in the two previous weeks; these 21 deaths were equal to an annual rate of 1·0 per 1000, exceeding by but 0·1 the mean rate from the same diseases in the 77 English towns. These 21 deaths from the principal epidemic diseases in the Irish towns last week included 9 from measles, 6 from infantile diarrhœa, 3 from whooping-cough, 2 from diphtheria, and one from typhus, but not one from scarlet fever, enteric fever, or small-pox. The 9 fatal cases of measles exceeded by one the number in the previous week, and included 7 in Dublin, and 1 each in Cork and Newtownards. Of the 6 deaths attributed to infantile diarrhœa (fewer by 4 than those in the previous week) 3 occurred in Dublin and 3 in Belfast. The 3 fatal cases of whooping-cough included 2 in Dublin and 1 in Belfast. Both the deaths referred to diphtheria occurred in Dublin; and the fatal case of typhus was registered in Belfast. The deaths referred to diseases of the respiratory system which had been 64 and 48 in the two previous weeks, rose again last week to 54. Of the 374 deaths from all causes in the 22 towns last week, 113, or 30 per cent., were recorded in public institutions, and 9 were referred to different forms of violence. The causes of 20, or 5·3 per cent., of the deaths registered in the 22 towns during the week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·8 per cent. in the 77 large English towns, and was equal to 3·4 per cent. in the eight principal Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: T. H. Vickers, to the *Africa*, additional, for Nore Subdivision, Home Fleet; G. Ross, to the *Victory;* A. Davidson, to the *Cormorant*, additional, for Gibraltar Hospital and for Dockyard duties; and E. F. Ellis, to the *Wildfire*, for R.N. Barracks and Sheerness Dockyard. Surgeons: J. S. Austin, to the *Victory;* L. C. Rowan-Robinson, to the *Victory*, additional, for disposal; and P. M. Rivaz to Devonport Dockyard.

ROYAL ARMY MEDICAL CORPS.

Colonel R. W. Ford, D.S.O., from the Military Hospital at Tidworth Park, Salisbury Plain District, has taken up duty as Administrative Medical Officer in the Woolwich District. Lieutenant-Colonel L. T. M. Nash has been granted six months' leave of absence home from India. Major W. Hallaran has been transferred from the Third (Lahore) Division and posted to the Military Hospital at Jhansi. Major I. A. O. MacCarthy, from Guildford, has taken up duty at Woolwich. Major M. Swabey, from Secunderabad, has been appointed to the Station Hospital at Wellington, Madras Presidency. Major C. T. Samman has been appointed Specialist in Mental Science to the Southern Army, India. Major W. H. S. Nickerson, V.C., has taken up duty as Officiating Sanitary Officer to the First (Peshawar) Division during the absence on leave of Major R. J. Blackham. Major H. G. Walton has been appointed Specialist in Advanced Operative Surgery to the Eighth (Lucknow) Division. Captain D. T. McCarthy has been transferred from the Seventh (Meerut) Division to the Eighth (Lucknow) Division for duty. Captain E. W. Powell has been granted leave of absence home from India

for four months. Captain A. McMunn, at present doing duty in the Dublin District, has been placed under orders for service in South China. Captain L. F. F. Winslow, from Pontefract, has joined for duty at Lichfield. Captain D. P. Johnstone has been transferred from Seaforth to Liverpool. Captain A. D. O'Carroll, from the Ambala Station Hospital, Sirhind District, Northern India, has been appointed to the Military Hospital at Aden. Captain J. B. Hanafin has been posted to Dehra Dun from Attock. Captain J. E. Hoar, on return from a tour of service in India, has been appointed to the Belfast District. Captain B. Johnson, from Wellington, Madras Presidency, has taken up duty at St. Thomas's Mount. Lieutenant F. H. Somers-Gardner, from Cosham, has joined at Gibraltar. Lieutenant T. H. Dickson, from the Dublin District, has been placed in Medical Charge of the Troops at Birr. Lieutenant R. C. Priest, at present serving at Colchester, has been placed under orders for a tour of service in India. Lieutenant D. E. C. Pottinger, from Glencose, has taken up duty at the Station Hospital, Lucknow.

Lieutenant-Colonel Henry L. E. White is placed on retired pay (dated July 3rd, 1911).

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of Colonel Aylmer Martin Crofts, C.I.E., to Surgeon-General (dated April 7th, 1911).

Lieutenant-Colonel B. B. Grayfoot has been appointed to officiate as Deputy Sanitary Commissioner for the Sind Registration District by H.E. the Governor of Bombay in Council, during the absence on deputation of Captain W. O'S. Murphy. The services of Lieutenant-Colonel F. Crimmin, C.I.E., V.C., have been placed by the Home Department of the Government of India at the disposal of H.E. the Commander-in-Chief. Lieutenant-Colonel D. T. Lane has relinquished charge of the duties of superintendent of the District Jail at Sialkot. Lieutenant-Colonel W. W. White has arrived home on leave of absence from India. Major T. H. Delany, civil surgeon at Shahabad, has been appointed Civil Surgeon at Saran, in succession to Major A. Gwyther, appointed to Howrah. Major H. Bennet has been appointed Civil Surgeon at Dharwar, in succession to Lieutenant-Colonel C. T. Hudson, who has obtained leave of absence. Major L. T. R. Hutchinson has been appointed to officiate as Professor of Pathology and Curator of the Pathological Museum at the Grant Medical College, Bombay. Captain E. C. Hodgson has been confirmed in his appointment as Medical Officer of Health, Simla, by the Home Department. Captain H. M. H. Melhuish, district plague medical officer at Amritsar, has been appointed in charge of plague preventive measures in the Delhi district. The services of Captain W. J. Fraser have been placed at the disposal of H.E. the Commander-in-Chief by the Home Department. Captain E. O. Thurston, Bengal Presidency, has received an extension of his leave of absence from India by the Secretary of State. Captain C. M. Goodbody has been appointed Civil Surgeon at Bikaner by the Foreign Department. Captain G. A. Jolly has been placed on temporary duty in the United Provinces of Oudh and Rohilkhand. Captain F. W. Cragg, on completion of his leave of absence home, has embarked for duty in the Madras Presidency. Captain V. B. Green Armytage has been appointed for duty in the Province of Eastern Bengal and Assam. Captain F. O. D. Fawcett has been granted six months' leave of absence home from India on medical certificate. Lieutenant F. F. S. Smith has been appointed Specialist in Ophthalmology to the Second (Rawalpindi) Division.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Highland Field Ambulance, Royal Army Medical Corps: Alfred John Williamson to be Lieutenant (dated April 21st, 1911).

3rd Home Counties Field Ambulance, Royal Army Medical Corps: James Barkley (late Lieutenant, Royal Army Medical Corps) to be Lieutenant (dated April 8th, 1911).

3rd Northern General Hospital, Royal Army Medical Corps: Captain Stanley Riseley to be Major (dated Jan. 3rd, 1911).

For Attachment to Units other than Medical Units.—Lieutenant Frederick William Kerr Tough, from the 1st West Lancashire Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated March 8th, 1911). Robert Wilfred Simpson to be Lieutenant (dated March 28th, 1911).

2nd Wessex Field Ambulance, Royal Army Medical Corps: Lieutenant Robert Burnet, from the 3rd East Lancashire Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated May 10th, 1911).

1st Northern General Hospital, Royal Army Medical Corps: Frederick George Armstrong, late Lieutenant, 1st Northumbrian Field Ambulance, Royal Army Medical Corps, to be Captain (dated May 12th, 1911).

3rd Western General Hospital, Royal Army Medical Corps: Surgeon-Captain Francis Griffith Thomas, from the 1st Welsh (Howitzer) Brigade, Royal Field Artillery, to be Captain, whose services will be available on mobilisation (dated July 5th, 1911).

For Attachment to Units other than Medical Units.—Percy Reginald Bolus to be Lieutenant (dated June 1st, 1911).

THE CARE OF THE WOUNDED IN A NAVAL ACTION.

What guiding principle will best direct the work of a medical officer in a naval battle? That is the question considered by a writer in the *Marine Rundschau* for June, commenting on a previous article (see THE LANCET, April 8th, p. 966), which detailed a well-thought-out plan for the satisfactory treatment of the wounded in an action on the lines that armies have found best. Here it is urged that that plan is too elaborate, requires too many assistants, and is founded on a misconception of the main duty of a medical officer in action. The conditions on board a ship differ so widely from those on a battlefield that similar measures can hardly be applied. In a ship men of all classes are intermingled, and in the same group of wounded not only must it be noted that some are lightly, some seriously, wounded, but that the loss of some of these means little to the efficiency of the ship, while the loss of others in responsible skilled positions is of grave importance, and these men the medical officer must at once treat if it is at all possible to get them back to their work, even if others more seriously injured have for the time to go unrelieved. In a sea-fight there are no reserves. A turret gun-layer or an important petty officer cannot be replaced if injured, but if he cannot be treated forthwith his training is lost to the ship for the rest of the fight. The case of an admiral wounded will occur to everyone. The medical officer must attend to him at once, and that on the spot where he was wounded, so that if he can be patched up at all the battle may not be lost for want of his directing hand. The principle, says the author, probably a layman, the guiding principle for the medical officer, as for every other officer and man on board, is to do all he can to help the ship to come out of action victorious. Interpreted for the medical officer, that means that it is the men who can be got back to their duty who are to be his first care, particularly those with great responsibilities and usefulness in the ship. This aim he must not allow to be clouded by his humane and professional instinct to devote himself especially to the most seriously wounded. By sending those others to duty, and so increasing the ship's power of damaging her enemies, he will be doing his best to ensure for the seriously wounded a more probable return to harbour and the benefits of hospital treatment by and by.

DEATHS IN THE SERVICES.

Brigade-Surgeon Thomas Edwin Burton Brown (Bengal Army, retired), C.I.E., late principal and professor of medicine at the Lahore Medical College, and chemical examiner in the Punjab, on June 28th, at his residence in Brondesbury, at the age of 78. He joined the Indian Medical Service in 1860, and retired in 1889, when he became medical tutor at the Ayherst Hostel, Cambridge.

LONDON HOSPITAL.—His Excellency the Hon. Whitelaw Reid will distribute the prizes to the students of the London Hospital in the library of the Medical College on Thursday next, July 13th, at 3 P.M.—The annual dinner for old students of the hospital, a function which has been increasingly popular during the past few years, will be held on Oct. 3rd at the Hotel Cecil, W.C. The chairman will be Mr. Douro Hoare. The secretaries are Dr. Lewis A. Smith and Mr. Frank S. Kidd.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—Your weighty but, from my point of view, much too moderate an expression of the views relative to National Insurance will, I trust, lead to the rejection of the principles upon which the Chancellor has based his Bill.

An enigma it certainly is, that so astute a politician should have introduced a Bill without the sanction of one of the most important of the parties concerned. There can be no doubt as to the objection of the members of our profession to contract practice, which was undertaken from motives of philanthropy in the first place and which has been forced upon us of late years as as objectionable necessity. The spirit of the age is one of compromise; the spirit of the medical profession has for many years past always been such. In connexion with the present legislative action valuable time has been wasted by the British Medical Association. The managers of this society accepted the principle upon which the legislation is based, and in so doing have jeopardised the cause. There appears to be little use in haggling over the details of a crazy structure, but there appears to be a great opportunity in fighting for the great principles which you in your leading article enunciate. The principle, which Sir Alfred Pearce Gould recently advocated, of payment for work performed is the right one for which to fight.

I have referred to our objections to contract practice. There is no doubt that the Bill rivets the shackles of it irrevocably upon our shoulders, however much its details may be varied. It is a matter of certainty that now is the time to fight for a principle, and if the opportunity is lost no recurrence can ever be expected. May I suggest that your efforts should be directed towards the formation of an effective fighting force; compromise must be thrown overboard. I am, Sir, yours faithfully,

Hatfield, Herts, June 30th, 1911. LOVELL DRAGE.

To the Editor of THE LANCET.

SIR,—It is within my knowledge that certain members of the medical profession are inclined to sympathise with Socialism and to regard with approval the Socialist proposals for the nationalisation of the medical profession. I think these gentlemen get their ideas of Socialism from a comparatively small section of the Socialist movement, consisting mainly of members of the Fabian Society and of the Church Socialist League—people who do not really represent in the least the sentiments of the great body of Socialists. It may interest some of your readers to see what a prominent Socialist, really representative of the Socialism of the masses—Mr. Ben Tillett—has to say with regard to the medical profession in relation to the State Insurance Bill. These comments show the bitter class prejudice which Socialist agitators foster among those who would be masters of the learned professions if a system of nationalisation were ever established. I am, Sir, yours faithfully,

Hammersmith, June 28th, 1911. WILLIAM BULL.

[ENCLOSURE.]

Extracts from a signed article by Mr. Ben Tillett appearing in *Justice* on Saturday, June 11th, 1911:—

I should sum up the dangers from the standpoint of the workers to be the dominance of the doctors, who in practice have been greedier extortionists than the worst of the grabbing lawyers so far as the Compensation Act is concerned. There should be a check on the doctors, and their malpractices should be punishable under similar conditions as the restrictions imposed by the Incorporated Law Society. This failing, the Board of Trade or Home Office should have power to withdraw the right to practise from those doctors who abuse their powers.

We should find some malingering under the Insurance Bill of the employers, insurance companies, doctors, and lawyers.

The "Won't Works" among the four groups of persons I have named from the standpoint of conscientious duty are many more than are the poor, wretched, half-starved creatures who may be termed "malingerers" by the sleek crowd of harpies and slugs of the social system. .....

The doctor class are making a sordid fuss over the present measure, but they have had the gain of the public charities, and have had victims to experiment on. They will have to be put in their place, and not to be the professional harpies as well as the licensed slaughterers of the human race. The maternity benefits are too small, and will merely pay the doctor's bill. .....

Already the gang of thieves in the shape of insurance touts, medical extortionists, employers' leagues and federations are "on the make." It is to be hoped the Labour Party will not be bullied or coaxed to relinquish a single benefit for the capitalists and their servants.

To the Editor of THE LANCET.

SIR,—I have received from the British Medical Association a form of pledge with regard to service under the Insurance Act. How can men be expected to pledge themselves when they know nothing of the conditions of service they will be offered? The Association should, I think, wait till at any rate the Bill is through Committee before talking about pledges. On these grounds I have declined to sign.

So far as one can see at present, the Bill will pass substantially in its present form. What will follow? Appointments on a contract basis (we may dismiss measured rate systems as too absurd for consideration—*vide* Dr. Pye-Smith's letter) will be offered by the larger Friendly Societies or by groupings of the smaller societies, or we may succeed in the Committee stage in getting this department of the Bill transferred to the local insurance committees. These appointments will be paid at a rate between 6*s.* and 8*s.* 6*d.* per annum. The men who have signed this pledge will, if they are men of honour, refuse to accept any such appointment. But the same considerations that have induced men to accept clubs at 2*s.* 6*d.*, and moreover to keep them when they have got established in practice—namely, the knowledge that if they did not take them someone else would—will force them to take these new appointments. In my own case—an industrial district with a population of about 3000 and no opposition of consequence—the appointment at 8*s.* 6*d.* would be worth £400 per annum. Is it possible to suppose that an appointment yielding a certain £400, with also the certainty of some private practice, would not soon be taken up? Think of the numbers of men working as locums and assistants, laboriously getting together a little capital before making their plunge into practice on their own account, think how they would jump at such an offer. And where should I be? I should see half my income gone at one stroke and the remainder following it in a year or two.

I ask, What can we do in anticipation of this catastrophe? There must be many thousands of doctors exactly in my position, each one considering how hard he will be hit by the new conditions, and whether he can afford to stand out or whether he must bend to the storm. To enable us to stand firm we must be assured that we shall not lose by it; we must know that if our practices are the ones to be split asunder by "blacklegs" we shall have the support, not merely the moral support but the financial support, of our fellows; in fact, we must establish a substantial fund to guarantee men against loss. Failing this, we shall be jockeyed out of our position by the various forces opposed to us. I am prepared to pay £5 5*s.* if 1000 other medical men will do the same for the expenses of a preliminary investigation into the feasibility of such a scheme. We should want a canvass of the whole Register; in many cases a personal canvass would be needed to ascertain the precise views of every man on the subject and what he would be likely to lose or gain under the Bill; and thus we could get some idea what amount of financial backing our fight would need. My idea is that if it were known that we had collected £20,000 to boycott the Bill we should hear very little further of it. I enclose my card, but for obvious reasons I do not wish my name and address published at present.

I am, Sir, yours faithfully,

July 1st, 1911. M.B. LOND.

INSTRUCTION OF SCHOOL CHILDREN IN HYGIENE.

To the Editor of THE LANCET.

SIR,—The executive councils of the National League for Physical Education and Improvement and of the National Health Society have had under their consideration Dr. Addison's Bill, which provides for instruction in hygiene and in the care of infants, and they have authorised us to express their earnest hope that the Bill may be allowed to become law.

If the health of the people is a great national asset provision for the due care of that h[illegible] is an act of national

insurance. To neglect the conditions which secure health is perilous, but the neglect which is so prevalent is due, not to heartlessness, but to ignorance. Due instruction therefore in the laws of health should not be a casual subject, but a necessary subject of education in our schools.

It is therefore in our judgment fitting that, to quote the terms of the Bill: "Each local education authority shall arrange, as hereinafter provided, that during each school term simple instruction in hygiene and the care of health, suitable to the age and understanding of the children, shall be given to all children attending public elementary schools, and, in particular, shall arrange that each girl of the age of 12 years or more shall be adequately instructed in the care and feeding of infants."

We therefore cordially welcome Dr. Addison's Bill and trust that it may receive the unhesitating support of all who desire national well-being.

Signed on behalf of the executive councils of the above societies,

W. B. RIPON.	HENRY KENWOOD.
LAUDER BRUNTON.	F. N. KAY MENZIES.
JOHN TWEEDY.	A. WELLESLEY HARRIS.
MARY SCHARLIEB.	F. LANKESTER.

Tavistock-square, London, W.C., June 28th, 1911.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—On previous occasions we have felt it incumbent upon us to reply to communications in your columns and elsewhere from the pen of Major H. C. French. Hitherto our difference of opinion has centred in what we regard as the unreasonable antipathy of Major French to the intramuscular injection of insoluble salts of mercury in the treatment of syphilis. We may say that since April 1st, when we observed a note from his pen in the *British Medical Journal*, chronicling at second-hand a death at Cairo, we have expected to see an article by him containing all the evidence that can be collected against salvarsan. In your issue of June 24th, p. 1691, our patient anticipation was rewarded.

It is not our intention to deal exhaustively with Major French's long and discursive criticism, but we feel we must take exception to a few of his statements. Like other opponents of salvarsan, he has something to say about the commercial aspects of the matter, but this by the way. His statement that the remedy was placed on the English market shortly after August, 1910, at which date "under 1000" cases had been treated by it, is grossly inaccurate. Salvarsan was not placed on the English market till after Dec. 8th, 1910, upon which date Professor Ehrlich delivered an address in Frankfort, and summed up the results obtained from the many thousand injections which had been administered during the preceding 10 or 11 months.

We have rarely come across a more egregious example of *suggestio falsi* than is contained in the following sentences: "I have previously emphasised the fact that atoxyl used in the treatment of sleeping sickness caused total blindness in 54 and partial blindness in 136 cases. Soamin and arsacetin ..... have also caused epileptiform seizures, atrophy of the optic nerve, and blindness in treating syphilis. I am not aware, however, of any fatal results as is the case with salvarsan." Now, these sentences are calculated to produce an impression upon the minds of the uninitiated that in addition to producing fatal results salvarsan is responsible for many cases of blindness. That such an idea is absolutely without foundation anyone who has studied the literature knows. The opponents of salvarsan write as though optic neuritis and optic atrophy did not occur in the course of ordinary cases of syphilis. During the last few months we have seen two cases of optic atrophy and one of optic neuritis, which had been treated throughout with mercury. If these cases had received an injection of salvarsan what a hue-and-cry their publication would have caused among the opponents of Ehrlich's remedy. As for disturbance of the sense of hearing, it is a common symptom of syphilis even when no arsenic has been exhibited. The question of fatalities is one of extreme importance, and with much effort Major French has collected 31 cases, 14 in infants and 17 in adults. Our study of the literature has led us to the opinion that some of the infants would have died in any case, whatever remedy had been employed. We do not regard the remedy as a suitable one for direct administration to young children. As for the fatalities in adults, some of them were due to errors in judgment in the choice of cases and others to a faulty technique.

If Ehrlich's careful instructions not to use the remedy in cases of degeneration of the circulatory system and brain syphilis had been followed, some of these deaths would have been avoided. It is very hard on any remedy, and on its discoverer, that it should be made the scapegoat for the errors of its administrators. One more statement we must take exception to, and that is that "syphilis, unlike cancer, sleeping-sickness, and kala-azar, is not a fatal disease." We wonder in what fool's paradise Major French has been living. Judged, of course, by the Registrar-General's returns, syphilis is not a fatal disease, for many a death directly due to it is certified euphemistically by another name. But surely Major French knows of the long series of life-destroying sequelæ that follow close in the footsteps of syphilis. It is because we regard syphilis as a most formidable disease that we advocate the administration of such a powerful remedy as salvarsan.

If Major French will for a few months make a careful use of it in suitable cases of syphilis we are confident he will be well pleased with the results, and will regret having written such an alarmist article, and one so calculated to create prejudice in the minds of those who, like himself, have had no personal experience of salvarsan.

We are, Sir, yours faithfully,

G. STOPFORD-TAYLOR.
R. W. MACKENNA.

June 26th, 1911.

To the Editor of THE LANCET.

SIR,—THE LANCET of June 24th contained a paper on the above subject by Major H. C. French, R.A.M.C. In my opinion his conclusions are erroneous, and appear to be based on a very small personal experience and an inaccurate interpretation of second-hand evidence.

In the first paragraph he states that "the drug apparently acts very much in the same manner that iodide of potassium does, and in early syphilis is not an actual curative agent." It has, however, been frequently shown that potassium iodide has little or no action on the Wassermann reaction on the treponema pallidum, whereas salvarsan produces a negative Wassermann in a large percentage of cases[1] and causes a very rapid disappearance of the treponema pallidum. On what practical experience does Major French base his opinion that "injections of salvarsan are not of greater value than administration of arsenic by the mouth"?

In the fourth paragraph Major French writes: "Up to August, 1910, there were under 1000 cases treated (by salvarsan), and it was placed on the English market very shortly afterwards." The foundation for this statement is based on an extract from an article by Bohac and Sobotta which was reproduced in Bresler's book in which these authors state that they have not found records of some effects that they have related "in the 1000 or more cases *published*." Now Ehrlich definitely states in "Die experimentelle Chemotherapie der Spirillosen" (p. 139), which was written before Oct. 5th, 1910: "I have before me the reports on over 9000 cases treated with salvarsan," and the drug was not placed on the the market till more than two months after this statement was written. Major French then calls to his aid the "31 deaths within a year"—a ghost which has been laid for many months and which might, I think, be permitted to rest in its dishonoured grave. Most of the cases quoted by Major French are discussed in the review of the subject by A. Manuel and myself.[2] In most of the few fatal cases either the technique was faulty or the contra indications were not observed. Some were desperate cases in which death occurred in spite of and not because of salvarsan.

Major French complains that Gibbard and Harrison were vague as to the period that elapsed between the injection of salvarsan and the disappearance of lesions in their cases. These authors reported the average length of time for disappearance of symptoms in 97 cases of primary or secondary syphilis, besides referring to 33 cases intractable or intolerant to mercury in which salvarsan produced a rapid change for the better. On carefully reading through their paper[3] it

[1] Manuel and Bayly: Practitioner, June, 1911.
[2] Ibid.
[3] Gibbard and Harrison: THE LANCET, March 18th, 1911.

will be seen that practically all their cases are accounted for, and I am therefore at a loss to understand what Major French has to complain of in their valuable contribution.

Regarding Major French's remarks on the injection of 0·2 grm. at fortnightly intervals, entailing a stay in hospital for six weeks, the paper in question gives no authority for his deduction that the patients remained in hospital during the whole of their treatment. I have since inquired on this point of the officers concerned, and find, in fact, that the detention in hospital was for only 24 hours after each of these small doses. Major French infers that Gibbard and Harrison confused the diagnosis by local treatment of the sores, but these officers state[4]: "In all cases of primary sore T. pallida were found in great numbers previously." I have been unable to find any justification for the statement that Gibbard and Harrison "claim 90 per cent. cures." On the contrary, these officers merely stated the number of relapses up to date and refrained from any comment.

As regards the "ocular casualties" and "labyrinthine disturbances" mentioned by Major French, Ehrlich categorically states[5] that no case of blindness has been reported to him, and that, despite penetrating research, it has not been possible for him to run one of these rumoured cases to earth. Professor Neisser in the Cavendish lecture (June 26th) stated that in his opinion the rare auditory symptoms were due to the disease and not to salvarsan.

It is impossible in a short letter to fully criticise Major French's paper or to reply in detail to all his arguments and conclusions. Dr. Alexander Manuel and myself have reviewed the matter at some length in the June number of the *Practitioner*, where I think that answers will be found to most of Major French's arguments. May I here point out that through a printer's error the percentage of fatalities was in the *Practitioner* placed at 2 per cent. instead of 0·2 per cent.? I cannot see the force of Major French's references to atoxyl, soamin, &c., in connexion with this subject, as these preparations differ as essentially from salvarsan as chloral does from chloroform.

Will Major French produce evidence that half a dozen workers have definitely abandoned the routine use of salvarsan after intravenous administration in 100 cases? I am still waiting for definite opposition to salvarsan based on practical experience of its use in a considerable number of cases. So far the English critics of salvarsan (Mr. Ernest Lane, Dr. C. F. Marshall, and Major French) appear to have relied either on very slight experience of the intramuscular method or on the careful gleanings from the reports of the few opponents and the remarkably small casualty list. As time passes even this very short list of casualties and serious after-effects is rapidly becoming proportionally less and less, and Professor Neisser is convinced that salvarsan should be given as a routine treatment in every case of syphilis and parasyphilis that does not present well-marked contra-indications. He considers salvarsan less harmful and dangerous than a prolonged course of mercury. Major French's conclusions, therefore, that salvarsan "is far inferior to mercury" and that "it is quite unjustifiable to use salvarsan in place of the judicious use of mercury in average cases of syphilis" appear to have been arrived at on insufficient data, and are not borne out by the large mass of evidence now at our disposal.

I am, Sir, yours faithfully,

HUGH WANSEY BAYLY,
Pathologist to the London Lock Hospitals, &c.

To the Editor of THE LANCET.

SIR,—Referring to the paper by Major H. C. French, R.A.M.C., entitled, "Salvarsan ('606') and Mercury in the Treatment of Syphilis," which appeared in THE LANCET on June 24th last, we wish to correct an inaccuracy appearing on p. 1691—viz., "I understand that it was originally stated that 'salvarsan' would not be placed on the market until 20,000 cases had been treated by it. Up to August, 1910, there were under 1000, and it was placed on the English market very shortly afterwards."

The true facts of the case are as follows: "Salvarsan" was only placed on the market generally (not only on the English market) on Dec. 15th, 1910, by the Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst-on-Main, Germany, after 60,000 doses had been supplied free of charge for testing purposes, with which about 40,000 cases were treated.

We beg to add that we have the authority of his Excellency Professor Dr. Paul Ehrlich for making the above statement, and remain, Sir, Yours faithfully,

Pro MEISTER, LUCIUS, AND BRÜNING, Limited,
St. Mary Axe, London, July 5th, 1911. ERNEST SCHOLL.

BRIGHTON SCHOOL CLINIC: THE ACTION OF THE HOSPITALS IN RESPECT OF DENTISTRY.

To the Editor of THE LANCET.

SIR,—In your annotation on the Brighton School Clinic on June 24th you remark on the subscriptions to hospitals for the purpose of obtaining letters to be given by the school doctor to school children requiring medical or surgical treatment. The honorary medical officers of all the hospitals have objected to this course, and the boards of management have all passed the following resolution:—

> That after the year 1911 the hospitals shall, except in special cases, decline to treat school children attending the primary schools of the Brighton and Hove education authorities, and found, on medical inspection by the medical officers of the said authorities, to be suffering from otorrhœa, enlarged tonsils, adenoids, errors of refraction, skin diseases, or defective teeth.

The Brighton education authority will thus have to arrange to have these cases dealt with in future without making use of charitable institutions. It is hoped that the honorary medical officers of hospitals in London and other towns will also refuse to do the Government's work for nothing.

I am, Sir, yours faithfully,

WALTER BROADBENT, M.D. Cantab., M.R.C.P. Lond.
Brighton, June 29th, 1911.

CYCLIC VOMITING.

To the Editor of THE LANCET.

SIR,—I am greatly interested in Dr. Edward Mellanby's very illuminating article on this subject which you publish in your last issue under the title "A Short Chemical Study of a Case of Cyclic Vomiting, with Some Remarks on Creatinuria and Acidosis." It deals with matters of considerable importance and beyond the scope of this communication, but there are one or two points which may well be commented upon at this stage. I think Dr. Mellanby is mistaken in believing that the general trend of opinion is in favour of ascribing to acid intoxication the symptoms which characterise cyclic vomiting, and, one may add, post-anæsthetic vomiting, the pernicious vomiting of pregnancy, and the other members of this closely allied morbid group. In recent years this view has been opposed in many articles and discussions. Rochford in 1904 attributed cyclic vomiting to an auto-intoxication due to incompetence of the liver, and strongly expressed his opinion that the presence of acetone, diacetic acid, and β-oxybutyric acid was in no way connected with its etiology. Leonard Guthrie at the Sheffield meeting of the British Medical Association in 1908, and again in discussion on a case shown before the Royal Society of Medicine in March, 1911, was of opinion that the symptoms of this condition could not be attributed entirely to acid intoxication, and Bainbridge, in the discussion which followed Guthrie's paper at the British Medical Association's meeting, pointed out that there was no proof available to show that acid intoxication was concerned in the production of any condition ascribed to it except diabetic coma. Hunter, in his article on delayed chloroform poisoning in Allbutt and Rolleston's "System of Medicine," also states his belief that the toxæmia in these conditions is due to something more than the products of fat katabolism. These are only a few examples from the recent literature on the subject, and I think they show that there is an increasing tendency to disparage the importance of acid intoxication as a cause of cyclic vomiting and allied conditions. Dr. Mellanby does me the honour of quoting my suggestion that the alimentary canal may be the source of a toxin or toxins which cripple the liver, weakening its powers of dealing with fats and so producing an acid intoxication. His article certainly helps to strengthen the first part of the hypothesis—namely, that the alimentary canal is the source

of the toxin or toxins. With regard to the second part, which ascribes to acid intoxication the symptoms of the condition, I should like to take this opportunity to say that I have long thought it untenable, and am quite prepared to accept the conclusion which Dr. Mellanby has arrived at as the result of his investigation, that cyclic vomiting is in no sense an acid intoxication. The presence of the acetone series in the urine is no more than a somewhat unreliable indication of a more profound lapse from metabolic rectitude in which the liver plays the chief part.

Even in diabetic coma it is quite legitimate to doubt the importance of the acidosis, since diabetic patients will gradually sink into coma and die, even when enough alkali has been administered previously to render the urine strongly alkaline for several days before death, and experimental injection of each of the known bodies of the acetone series fails to reproduce the symptom-complex known as diabetic coma.

I am, Sir, yours faithfully,

Queen Anne-street, July 3rd, 1911. FREDERICK LANGMEAD.

THE DECLINING BIRTH-RATE.

To the Editor of THE LANCET.

SIR,—In Mr. F. E. Fremantle's Edward Jenner lecture on "The Declining Birth-rate," published in THE LANCET of April 22nd, we read (p. 1061): "The chief factors, then, in the decline of the birth-rate are mechanical and logical. The mechanical factors just named are in reality only methods. It is the following logical factors that are the ultimate cause." Mr. Fremantle then gives as the logical factors (though what he quite means to connote by "logical" is not very obvious) three conditions of married life which may be shortly summarised as: 1. Child-bearing at long intervals in the interests of health. 2. The interferences to child-bearing caused by social or conjugal obligations. 3. The desire for economy.

Surely, to any honest and impartial student of the present-day conditions of married life the most potent cause of the decline in the birth-rate of Great Britain, except perhaps among the very rich and the very poor, is *compulsory barrenness*. If Mr. Fremantle will pardon me for saying so, I think he might have made his lecture more illuminating and no whit less scientific if he had first read and considered the remarkable preface to Mr. George Bernard Shaw's play *Getting Married*. Therein he would have had the opportunity of learning the indubitable fact that the class of women from whom the nation has perhaps most to expect—i.e., that class generally termed the "middle classes"—is from a variety of causes, all of which are fully discussed by Mr. Shaw in his inimitable style, opposed to the law which involves "the saddling of the right to a child with the obligation to become the servant of a man."

The medical profession can do all that Mr. Fremantle suggests, but until the medical profession throws its influence on the side of those who are striving to attract public attention to the lamentable state of the English marriage and divorce laws very little hope can be reasonably entertained that the fall in the birth-rate in the British Isles is going to stop. Mr. Fremantle also advocates that all aids to the prevention of conception "should be relentlessly pursued and checked by the law." Does he propose that a married couple should cease from sexual relationship if for any reason, and indeed there are many, conception should be highly undesirable? If Mr. Fremantle does propose that, and it is difficult to construe any other meaning to his remark, does he reflect on all that is almost sure to follow upon such procedure? It is inconceivable that he should not have come across many cases of chronic mental disorder which are directly attributable to sexual repression, especially so in married persons separated from each other either through the rough calls of duty or business, as well as among men or women who have recently lost either wife or husband.

Further, I venture to believe that Mr. Fremantle greatly overrates the disorders which are indubitably referable to the prevention of conception; the production of abortion is another thing altogether, and no doubt under this heading many disorders can be enumerated. An absolutely impartial investigation of data on the dangers attributable to the prevention of conception would lead one to suppose that there is only one serious disorder to be feared from the practice of preventing conception—i.e., hysteria in certain forms.

In conclusion, I would venture to assert that the propagation of a sound systematic instruction in sexual hygiene, coupled with a thorough revision of the laws connected with marriage and divorce, will do more to correct the decline in our birth-rate than any of the suggestions put forward by Mr. Fremantle in reference to the suppression of the mechanical means of preventing conception or the *modi operandi* of producing abortion.

I am, Sir, yours faithfully,

OWEN A. R. BERKELEY HILL, M.A., M.B., Ch.B. Oxon.

Saugor, Central Provinces, India, May 11th, 1911.

ANÆSTHETICS IN INTESTINAL OBSTRUCTION: THE VALUE OF GASTRIC LAVAGE.

To the Editor of THE LANCET.

SIR,—The possibility of immediate or gradual suffocation or of ensuing broncho-pneumonia in these cases is well known, but I have some reason to think the extent of the danger is not always realised. Unless special measures are taken there is this dilemma—that under a light anæsthesia rigidity and straining make the operation prolonged and difficult, and tongue retraction and laryngeal spasm entail asphyxia and cardiac dilatation; whilst under a deep one ejection of the stomach contents may still go on, and as cough reflex is abolished the patient is likely quietly to be drowned.

It is, of course, necessary for the anæsthetist to be very watchful, and it is the usual practice to keep the head low and on one side, with the opposite shoulder raised, the mouth open, and sponges ready. As Mr. Colt in his letter in your columns on June 17th also mentions tongue forceps, I would point out that it is a common and disastrous mistake of nurses and others to push the lower jaw forwards or pull out the tongue whilst a patient is in the act of vomiting. By so doing the natural closure of the larynx is interfered with and the risk of inhalation of fluid increased. This should not be done until ejection has ceased and after clearing the pharynx. If breathing should be dangerously arrested during ejection it would, I believe, be safer to perform laryngotomy. It would certainly be hazardous to leave a deeply anæsthetised patient in charge of a nurse under such circumstances. If the Trendelenburg position be adopted during operation fluid is apt to run down continuously, forming a pool in the pharynx, which cannot be kept clear even by frequent sponging.

Preliminary lavage of the stomach, as remarked by Mr. Colt, often proves a failure, but I can hardly agree that if properly done it is a severe strain on the patient and causes much pharyngeal irritation. This should at least be carried out, even when vomiting has not been a marked symptom. I have recently drawn attention[1] to the importance of doing so, at any rate when the operation has been concluded. Sometimes a stomach-tube may be left in and connected to a long tube for syphonage, but it may interfere with respiration or fluid may well up around it, so there is no complete security against inhalation.

In a paper contributed to one of your contemporaries in 1908 I suggested the advisability of preliminary laryngotomy or tracheotomy to obviate these difficulties, and Dr. Dudley Buxton[2] has described the method at length and urged its employment. Laryngotomy can be done very quickly under local or light anæsthesia; it should cause little bleeding and no shock; the wound should heal in a few hours. The pharynx and upper larynx are cocainised and well packed with gauze all round the stomach-tube.

There are no further difficulties and dangers in regard to the respiration or the anæsthetisation, and the operator is not hurried and disturbed. In short, the advantages of the proceeding are as great as in such operations as removal of the tongue, and I trust it may be more generally adopted than is the case at present.

I am, Sir, yours faithfully,

Chelsea, S.W., June 19th, 1911. J. D. MORTIMER.

THE EYESIGHT OF SAMUEL PEPYS.

To the Editor of THE LANCET.

SIR,—I have read with interest the address of Mr. D'Arcy Power to the Samuel Pepys Club. As a literary achievement it shows both industry and ingenuity, but the arriving at a definite prescription for Samuel Pepys, Esq., seems to suggest that the modern quack method of "diagnosis and treatment by correspondence" need no longer be viewed with professional disfavour. The ease with which a specialist, on hearing Pepys' symptoms, at once prescribed "+2 D. or +2·5 D. convex glasses" is very striking, as is also the facility with which Mr. Power himself added +0·50 cylinders axis 90°. Of course, Samuel Pepys cannot try these spectacles, and there is therefore no means of bringing home to the prescribers any possible error arising out of the "correspondence" method, but the whole episode casts a somewhat lurid light on the specialist and his work. I am not well enough versed in optics to criticise the theoretical accuracy of the prescription, but it would really be interesting to know on what grounds the "axis 90°" was arrived at in the unavoidable absence of the patient; it seems "uncanny," if it is not a little joke.

I note that Mr. Turlington advised Pepys against using "reading glasses which do magnify much," and that Mr. Power characterises this advice as "superlatively bad, for he was clearly recommending Pepys to use concave glasses when in reality he needed convex ones." On the face of it this is not so clear. I understand that concave glasses do not magnify at all, but rather diminish the size of an object. There is surely significance in Turlington's word "much," and it might be more fair to interpret his advice as a wise recommendation to use the lowest convex glasses that the patient could read with, rather than indulge in the luxury of much magnification. The literal terms of the advice can hardly be said to suggest concave glasses.

Incidentally, it does seem a pity, as Mr. Power suggests, that Mr. Pepys did not "sit upon his tubes and crush them," seeing that a revolution of the laws of dioptrics was so imminent, and depended with a fair amount of certainty on such a likely accident. It looks as if Providence had missed a splendid opportunity.

I am, Sir, yours faithfully,

Liverpool, June 22nd, 1911. A. ROSS CARMICHAEL.

EMOLUMENTS IN THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—In your annotation in THE LANCET of May 13th with reference to "M.B.'s" letter *re* the Indian Medical Service you rightly state that it is Lord Morley's disastrous suggestion to cut down the civil appointments at present held by the Indian Medical Service that has so harmed the service, but at the same time you seriously underestimate the bad pecuniary emoluments of the Indian Medical Service. As an example of the small opinion the Indian Government have of the worth of their medical men, the Royal Engineers at home draw less pay than officers of the Royal Army Medical Corps of corresponding ranks at home. In India the reverse is the case, and not only this, but the R.E. officer draws more than an I.M.S. officer of corresponding rank. You must remember that an R.E. gets his professional education at Government expense. An officer of the Royal Army Medical Corps draws actually *less* pay in India than while serving at home (officers of the Indian Medical Service draw slightly more pay than the Royal Army Medical Corps). Eighteen months ago the pay of the Indian army officers was raised and not the Indian Medical Service, so that now these officers draw practically the same pay as the Indian Medical Service in spite of not having had the previous long expensive education a doctor has to undergo.

When an R.E. officer goes into civil, he draws considerably more pay than in military employ. An I.M.S. officer, on the other hand, draws 50 rupees less. For many years a civil surgeon will make practically nothing in private fees. Also, there is such a block in civil now, that one cannot get in under about eight years' service.

Another crying grievance of the Indian Medical Service is that the cadre is kept so small that leave is extremely hard to get. One is entitled to two months' privilege leave every summer, but, as a matter of experience, one is lucky to get it on an average every other year. Leave home, too, is extremely hard to get. Officers who have been serving for over five years find they are unable to get leave owing to the shortage. Then again the number of transfers a junior officer gets is nothing short of a scandal. One constantly hears of junior officers having 12 or 13 transfers in his first three or four years.

I am afraid I have sent rather a long letter. You seemed surprised that "M.B." should state that living has gone up 100 per cent. and the purchasing power of the rupee down 50 per cent., but this is well recognised out here. Polo, shooting, &c., are rapidly becoming the rich man's sport as in England.

I am, Sir, yours faithfully,

May 31st, 1911. I.M.S.

THE BUBONIC PLAGUE IN EGYPT IN 1911.

To the Editor of THE LANCET.

SIR,—The apparent indifference of the authorities and of the public to the ravages of the plague in Egypt is very singular. From the commencement of this year to June there have been more than 1400 cases, compared with some 700 in the corresponding period of 1910. For the week ending June 3rd the returns indicate a slight diminution in the number of cases, perhaps owing to the weather, but the innumerable rats in the villages are probably becoming more universally affected. The provinces which this year have suffered most severely are Assouan, with 491 cases, of which 307 proved fatal; Keneh, 505 cases, 392 fatal; and Assiout, 186, of which 93 terminated fatally. The type in some places is most virulent. Last December a native sanitary officer, despatched to endeavour to combat an outbreak in a village in the Delta, caught the infection the day after his arrival and died within 24 hours. This failure to wage successful warfare against the plague is due to the attempt to try natives in posts previously assigned to Europeans. In the sanitary department in country districts, unless British officials are augmented in number and authority, and thus certain necessary precautions and cleansings enforced upon the fellahin, a recrudescence of the plague, with its attendant misery and injury to the tourist season, is much to be dreaded.

I am, Sir, yours faithfully,

June 24th, 1911. TRAVELLER.

A YEAR'S COST OF RUNNING A MOTOR-CAR LIMOUSINE COMPARED WITH THAT OF A BROUGHAM.

To the Editor of THE LANCET.

SIR,—A year ago I changed my brougham for a motor-car. The brougham, two horses and a coachman, and all other expenses, including all renewals, cost on an average £210 a year. The mileage was estimated at 4000 = 1*s.* 0½*d.* per mile. The carriage was used for the purposes of the practice only, one horse in the morning and the other in the afternoon. The initial cost of a 15 h.p. Daimler Limousine, ready for the road, with spare wheel and all accessories, was £543; the initial cost of brougham, two horses, harness, &c., would be nearly £300. The first year's expenditure on the car, including chauffeur (£90), insurances, rent, rates, petrol, new tyres, and all other expenses, amounted to £201 2*s.* 1*d.*, to which £108 12*s.* 2*d.* must be added for depreciation (i.e., 20 per cent. of initial cost); the total expenses for one year were, therefore, £309 14*s.* 3*d.* The miles run in the year were 5203, of which 1128 were for pleasure and 4075 for professional purposes. The cost of running per mile works out at 1*s.* 2¼*d.* Therefore £241 19*s.* may be stated as the cost of the car for one year to the practice as compared with £210 for the brougham. The total petrol used for all purposes was 294 gallons, or 17⅝ miles to the gallon. As 500 miles were run with a defective carburetter which gave only 10 miles to the gallon in the town with frequent stoppings, and only 13 miles in the open country, and as on a holiday 816 miles were run on 35 gallon

(= 23½ miles to the gallon), it is obvious that the mileage per gallon of petrol now will be about 20 in the town, in which the motor runs about 14 miles a day and stops and starts about 30 times.

The tyres on the steering wheels are an expensive item. The four wheels of the car and one spare wheel were fitted with Continental tyres with the following results:—One front wheel plain tyre is still running at 5293 miles; one front wheel plain tyre burst at 5160 miles; one rear wheel studded tyre split at 1851 miles; one rear wheel studded tyre ran only 2565 miles when most of the studs were out and the cover was worn through. Avon tyres were then tried. One rear wheel studded tyre ran only 2245 miles when most of the studs were out; it was then retreaded and put on a front wheel. A rear wheel cross-grooved Avon has run only 1300 miles and is now off for repairs, it having a big cut in it as well as a patch of the canvas exposed. Other tyres of the same makes gave like results. Many of the streets of my town are paved with rough cobble setts, which I think pull out and wear the studs quickly. I am therefore using now plain tyres on the back wheels as well as on the front. Altogether I spent £30 6*s*. 7*d*. on tyres in the twelvemonth.

The only mechanical breakdown in the year was caused by the breaking of a ball race which prevented the use of the car for a day and a half. It occupies the chauffeur two to three hours each day to keep the car smart and in running order. The great advantages of the car are obvious—viz., greater speed, and therefore saving of more time each day for either leisure or study. Ease and comfort in travelling, and also more light in a Limousine. The rapid motion through the air is exhilarating, whilst trundling along in a brougham is somewhat depressing. The car never tires as horses do. Long journeys do not upset the day's work as formerly, since they can be taken in so short a time.

The advantages of a Limousine over a landaulette or open body are: No need to alter one's dress nor to wrap up in cold or wet weather; with the windows down between the body and the chauffeur, no draught, yet more air and more light than in a brougham. All the parts being fixed, they do not rattle loose as in a landaulette, nor does dust blow into the body or on to the occupant. Then there is the pleasure and health derived from touring and the advantages of having a rapid mode of travelling at one's command at any time during the day or night. With a silent Knight engine the absence of vibration and noise is a great advantage to a doctor and his patients. I should say that to a busy man an experienced, steady, and trustworthy chauffeur is a *sine quâ non*.

I am, Sir, yours faithfully.

June 30th, 1911. F.R.C.S. ENG.

MEETING OF CANADIAN MEDICAL ASSOCIATION IN MONTREAL.

(FROM A SPECIAL CORRESPONDENT.)

THE forty-fourth annual meeting of the Canadian Medical Association opened on May 7th. All the sessions were held in the Anatomical Laboratory of the new medical building of McGill University, Montreal, except that the address in medicine was delivered in the gallery of the Art Association.

At the general meeting the President-elect, Dr. GEORGE E. ARMSTRONG, of Montreal, was installed, and addresses of welcome were given by Dr. GUERIN, mayor of Montreal, himself a medical man, and by Dr. PETERSON, Principal of the University. Some business matters were attended to and the report of the Milk Commission of the Canadian Medical Association was read.

On the afternoon of Wednesday the section meetings began. The meetings of the section on Preventive Medicine were especially interesting, and it may be said that a symposium in this section on Typhoid Fever and Water-supplies was a conspicuous success. On Thursday morning a general meeting was again held in the Department of Anatomy, when the address of the President, Dr. G. E. Armstrong, was read. Unfortunately, Dr. Armstrong had had to leave the meeting on the previous day on account of illness, and was not sufficiently recovered to deliver his own address, which was therefore read in his absence by Dr. A. HUTCHINSON, of Montreal.

Presidential Address.

The address was largely concerned with a retrospect of the history of the rise and development of the association in Canada. A portion was devoted to a consideration of the Roddick Bill for Dominion registration, which Dr. Armstrong characterised as the most forward medico-political question before the profession in Canada to-day. He hoped that with the adoption of the Act before long the English-speaking provinces would unite on a uniform standard of matriculation, although Quebec would have to remain outside on account of different educational methods. Referring to the value of research work Dr. Armstrong declared that English researches of a century ago were the profitable milch cows of foreign nations to-day. In discussing the pure water problem Dr. Armstrong stated that in his opinion in such a country as Canada, with its abundant water-supply, it was a reproach to any municipality, great or small, to have water-borne diseases. The housing problem was next dealt with, and it was pointed out how much it had been intensified in Montreal and other cities by the introduction of swarms of immigrants, many with low standards of living and general habits which did not tend to healthy bodies, sound minds, or good citizenship. There ensued slum life and an inevitable degeneration amongst the third and fourth generations of city dwellers, with the result that a large proportion of people became charged upon the State. He therefore urged that the Canadian Medical Association should work to demonstrate to municipalities that money expended in providing the working classes with better houses, wider and better aired and lighted streets, would be infinitely well rewarded in a lesser expenditure for police-courts, prisons, asylums, and hospitals, thus inverting the principle that "The means to do ill deeds makes ill deeds done." Canadians had no excuse for repeating the mistakes of older civilisations and in this way they could best aid the churches and the temperance and moral reformers.

Address in Surgery.

Dr. A. PRIMROSE of Toronto delivered the address in surgery. The speaker said that being a young country something of the spirit of the pioneer settlers had been inherited, and thus Canadian medical men were more ready to develop along lines which might be new and revolutionary in character. The consequence of this adaptability and willingness to learn had been that nowhere was work done in surgery with more general efficiency than could be found in the hospitals of Canada to-day. Dr. Primrose, like Dr. Armstrong and all the principal speakers, both at the McGill celebrations and at the meeting of the Canadian Medical Association, paid heartfelt tribute to the memory of Dr. James Bell of Montreal, who died somewhat suddenly a few weeks ago. His great merits as a surgeon, a man, and a citizen were referred to in fitting terms. Dr. Primrose, while allowing that conservatism in surgery was good, said that pure prejudice often passed as conservatism, and therefore care should be taken that no prejudices were harboured and that conservatism should in no way be allowed to hinder better judgment. The speaker pointed out that in all ages the advance of science had been hampered by prejudice, and that even in these enlightened times prejudice was not dead. The technique of Lister, for example, did not make the headway that was its due, on account of the opposition of some of the distinguished medical contemporaries, and it was a remarkable circumstance that foreign surgeons had been more quickly convinced of the great value of antiseptic treatment than had those of his own country. Dr. Primrose eulogised Lord Lister as the almost perfect type of the logical scientific mind. He urged that medical students should have a prolonged and efficient course of instruction in preliminary science, and opposed the view held by many that such training was unnecessary. Reverting again to the question of conservatism in surgery Dr. Primrose said that although a conservative attitude was to be commended it should be that type of conservatism which was tempered with ability to use calm and deliberate judgment in determining what was best for the patient; and when new light was thrown on some obscure problem medical men should be ready to abandon any erroneous ideas which might hitherto have been held, and be prepared to advance, looking for no finality in present-day methods, but always endeavouring to attain the ideal.

Gall-stone Disease.

A paper on the Surgical Treatment of Gall-stone Disease was contributed by Dr. WILLIAM J. MAYO of Rochester, Minn., U.S.A. Dr. Mayo said that in reviewing 4000 operations performed by him and his brother he had been impressed with the fact that the mortality was due to the complications incident to the disease rather than to the removal of gall-stones from the otherwise normal gall-bladder. It was in the early period that operation furnished an easy, safe, and efficient cure. Cholecystostomy with temporary drainage of the gall-bladder to the surface was the operation preferred, because it saved this valuable organ for future functioning. The danger of re-formation of gall-stones after this operation was exceedingly small. In the class of cases in which the gall-bladder was contracted down upon a mass of stones secondary carcinoma was likely to develop. The danger of carcinoma alone was five times as great as the mortality following operations for the relief of simple gall-stone disease. So long as the stones were confined to the gall-bladder the trouble remained localised in an organ which was not essential to life, but with the entrance of stone and infection into the deep duct of the liver two fundamental organs which were essential to life were liable to be involved in the process—namely, the liver and the pancreas. Stones in the common duct not only impaired the health of the patient, but complications directly threatening life might arise at any time. In the Mayo brothers' 4000 operations the average mortality was 2·75 per cent. In 2920 of these the disease was local and confined to the gall-bladder and cystic duct. The operative mortality was 1·8 per cent. In 2165 of these cystostomy was performed, with a mortality of 1·5 per cent. In 755 cases cystectomy was performed, with a mortality of 2·4 per cent. In 492 cases in which the common duct was involved operation resulted in an average mortality of 8 per cent., a mortality which depended not so much upon the operation itself as upon the extent of involvement of the liver and pancreas, and the bad general condition of the patient. Pancreatitis as a complication occurred 359 times in the 4000 cases.

Address in Medicine.—Work in the Sections.

The address in medicine was delivered by Sir JAMES BARR.

Three symposia were held, one on acute poliomyelitis, one on temperature in the puerperium, and one on typhoid fever and water-supplies. The latter was very interesting and instructive, and its initiation was due to Dr. T. A. STARKEY, professor of hygiene at McGill University, and chairman of the Section of Preventive Medicine. The subject of typhoid fever was discussed from every standpoint, and the important point urged by the chairman was generally conceded, that in epidemics of typhoid fever there are usually, if not always, many cases of typhoid-like infections which are not true typhoid fever—that is, do not react to the Widal test. Nevertheless, such cases constitute a menace to a community, because if not looked after they will spread. This recognition of the typhoid-like infections is important. Mention might be made of many other excellent and valuable papers read in the different sections did space permit. As with the opening of the new medical building of McGill University, the hospitality of those responsible for the arrangements of the Canadian Medical Association was bounteous. Garden parties, teas, receptions, and excursions were the order of the day and evening, and as the weather was fine were thoroughly appreciated by the medical visitors, some four hundred in number. An especially pleasing feature of the general meeting was the presentation of a bound illuminated copy of the first issue of the *Journal* of the Canadian Medical Association to Dr. Andrew Macphail for his energy and great assistance in establishing this publication.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Edinburgh and the National Insurance Bill.

THE following resolutions with reference to the National Insurance Bill were passed by the Royal College of Physicians of Edinburgh at a meeting held on June 27th:—

1. That the medical profession should be adequately represented on—(*a*) the Insurance Commission; (*b*) the Advisory Committee; (*c*) the Local Health Committees.

2. That "medical benefit" and "maternity benefit" should be administered by the Local Health Committees and not by "approved societies."

3. That in respect of the administration of "medical benefit" the "arrangements with duly qualified medical practitioners" made by the Local Health Committees should be such as to admit of free choice of the medical practitioner on the part of the insured person; and that in respect of the administration of "maternity benefit" the like free choice of medical practitioner or midwife on the part of the person receiving "maternity benefit" should be admitted.

4. That it be enacted, that the drugs and medicines supplied shall be of the standard required by the British Pharmacopœia, and that the dispensing of prescriptions shall be carried out by legally qualified persons.

5. That in respect of the grant of subscriptions and donations to hospitals and other charitable institutions, contemplated in Clause 17 of the Bill, power should be given to Local Health Committees to grant subscriptions or donations to hospitals or other similar institutions.

6. That in "maternity cases" attended by a midwife, the Local Health Committee should be empowered to pay for the attendance of a medical practitioner should such attendance be called for by the midwife in accordance with the rules governing her practice.

7. That the capitation sum of 6*s*. which has been suggested for "medical benefits" is inadequate to secure the standard of medical attendance and drugs which is essential.

8. That in respect of the deposit contributor class, which will consist of members other than the picked lives of the friendly societies, a higher remuneration for medical attendance should be provided than in the case of those insured through Friendly Societies.

9. That the "medical benefits" under the Act be limited to persons whose average income from all sources does not exceed £2 per week.

Aberdeen Asylums.

In the annual report of the General Board of Commissioners in Lunacy for Scotland, the comparative absence of tuberculous disease in the causation of death in the Aberdeen Royal Asylum is specially referred to, and is ascribed to the satisfactory hygienic conditions in which the patients are placed, and to a suitable and abundant diet. During the year an old man of 90 died, who had been an inmate of the asylum for 68 years, probably a record residence. A considerable reduction has taken place in the use of restraint in the treatment of patients, and the efficiency of the medical treatment is commented on in the report in laudatory terms. In the Aberdeen City Asylum the cleanliness and brightness of every section of the institution are noted. The boarding-out of patients who no longer need the expensive and elaborate provisions of asylum care is receiving the attention of the Aberdeen parish council. As a result of reluctance on the part of relatives to consent to such examinations, post-mortem verification of the cause of death is in extremely low proportion. Provision of cottages for married attendants, it is hoped, will result in the retention of a trustworthy and well-behaved class of men. This is a most desirable aim, as three nurses and two attendants have recently been dismissed for ill-treatment of, or roughness to, patients. The management of the institution is regarded as capable and conscientious. In the Aberdeen county district there has been an increase of 19 insane persons, in Inverness an increase of 13, and in Shetland of 17. None of these increases can be attributed to increase in population, and the last constitutes an unusual increase in a small county with a falling population. Possibly some change in local administration may explain the increase.

July 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Bill: a Deputation to the Local Government Board.

THE committee of the Irish Medical Association appointed to wait upon Mr. Lloyd George reported to the meeting of practitioners held in Dublin on June 30th that the Chancellor of the Exchequer had referred it to the Irish Local Government Board, which would report to him its demands. Accordingly, on June 30th, the deputation met the three Commissioners of that Board in Dublin, and a long discussion took place. Apparently the Irish Board advised the Chancellor in reference to the Irish portion of the Bill and the Commissioners evidently supposed that all that was to be done was to increase the salary of the dispensary medical officers working the insurance scheme by the simple expedient of adding 2*s*. or 3*s*. per insurance patient per annum to the pay of the dispensary officers. They seem to have overlooked the fact that in Ireland, out of the 2724 members of the medical profession, about 810, or less than one-third, are dispensary

medical officers, and that in the towns, especially the industrial ones, such a scheme would be hopeless, for it would be an impossibility for the dispensary medical officers to do all the work; it would be grossly unfair to the other medical men in these towns, and in the sparsely populated poorer districts no more patients would be added to the dispensary medical officer's list, for practically he has to attend them all at present. Further, it must appear that the Local Government Board in Ireland thinks that if the scheme passes it would itself be the controlling authority, a policy that would be resisted. Finally, the Commissioner who presided admitted that they had never thought of the question of the voluntary hospitals in relation to the scheme.

The Medical Profession of Ireland and the National Insurance Bill.

A mass meeting of the medical profession in Ireland was held on June 30th in Dublin to discuss the relation of the National Insurance Bill to the interests of medical men. Although less than a week's notice had been given of the time and place of meeting, medical men attended from all parts of the country. The resolutions proposed and passed were based on the results of a referendum undertaken by the Irish Medical Association. They were as follows:—

1. That this mass meeting of the medical profession in Ireland approves of the following: (1) A total income limit of £2 a week for those entitled to medical benefit; (2) free choice of doctor by patient, subject to consent of doctor to act; (3) medical and maternity benefits to be administered by Local Health Committees and not by Friendly Societies; (4) the method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the medical profession of the district of that Committee; (5) medical remuneration to be what the profession considers adequate, having due regard to the duties to be performed and other conditions of service.
2. This mass meeting of the medical profession in Ireland approves—(*a*) That at least one-fourth of the Committee be medical practitioners, and statutory recognition of a local Medical Committee representative of the profession in the district of each Health Committee; and (*b*) that a special Insurance Commission be instituted for Ireland.
3. That in the event of a satisfactory settlement not being arrived at under the main conditions suggested by the above, we are prepared to refuse to administer the medical and maternity benefits under the National Insurance Bill.
4. That the Committee of Council of the Irish Medical Association and the Irish committee of the British Medical Association be appointed an executive committee to look after the interests of the medical profession in Ireland in connexion with the National Insurance Bill.

A resolution urging the total rejection of the medical clauses of the Bill was proposed and cordially received, but it was ruled out of order by the chairman.

Speech by Mr. Joseph Devlin, M.P.

On the evening of June 30th Mr. Joseph Devlin, who is the head of the Ancient Order of Irish Hibernians and who represents a thoroughly working-class division of Belfast, addressed his constituents in praise of the Bill. He pointed out, however, that it must be modified for the special circumstances of Ireland, and that in order to amend it to Irish needs a committee of the Nationalist Members had been appointed, and they were making satisfactory progress in their work.

Congress of the Royal Institute of Public Health.

It is expected that the Congress of the Royal Institute of Public Health, to be held in Dublin, will be one of the largest and most successful held. Matters relating to public health, the prolongation of life, and the prevention of diseases will occupy a good portion of the time, yet the social part will be well catered for. Garden parties will be given by the Countess of Aberdeen, Sir Christopher Nixon, Dr. H. Benson, and Mr. Stanley Cochrane. A reception and conversazione will be held in the Museum, and excursions to various places of interest have been organised. Ample accommodation will be provided in the centrally situated premises of Trinity College, and all the sectional meetings will be held there. Lady Aberdeen will deliver the Presidential address on the morning of Tuesday, August 15th, when it is expected that the President, Vice-President, and honorary secretaries of the different sections and others connected with the Congress will attend in their academic and municipal robes.

Congress of the Royal Sanitary Institute.

The twenty-sixth Congress of the Royal Sanitary Institute will be held in Belfast from July 24th to 29th. In the various sections and conferences the following subjects will be considered:—Sanitary Science and Preventive Medicine: "The Prevention of Typhoid Fever" and "Sewage Purification"; Engineering and Architecture: "The Planning of a Modern City, from an Engineer's Point of View," and "Model By-Laws in Relation to Architectural Practice"; Municipal Representatives: "Municipal Lodging Houses" and "Municipal Hospitals"; Port Sanitary Authorities: "Plague Precautions in Reference to the Destruction of Rats" and "The Importation of Unsound Food"; Medical Officers of Health: "The Notification and Treatment of Non-notifiable Infectious Diseases" and "The Medical Officer of Health in Ireland"; Engineers and Surveyors: "The Discharge of Sewage into Tidal Waters" and "The Dust Nuisance, its Evils and Abatement"; Veterinary Inspectors, "The Hygiene and General Arrangements of a Modern Slaughterhouse" and "Meat Branding and the Uniformity of Meat Inspection; Sanitary Inspectors: "The Smoke Nuisance and its Abatement" and "Dairies and Milk-supply from a Sanitary Inspector's Point of View"; Women in Hygiene: "The State Endowment of Mothers" and "The Reduction of Infant and Child Mortality from Measles"; and Hygiene of Childhood, "The Hygiene of School Life" and "Infant Mortality in Towns." By an error, a sentence referring to this congress was inserted in the programme published last week of the August congress in Dublin of the Royal Institute of Public Health.

Diphtheria in Belfast.

At the monthly meeting of the Belfast city council, held on July 3rd, it was stated that in an area having its centre at Chichester Park, and a radius of about half a mile, there were 17 cases of diphtheria, 16 of which received their milk from the same dairy, and that in "swabs" taken from the family of the dairyman diphtheria bacilli were found. Between May 14th and June 17th 92 cases of infectious disease were notified—3 of typhus fever, 4 typhoid fever, 42 scarlet fever, 2 puerperal fever, 29 diphtheria, 1 membranous croup, and 9 erysipelas. There were also 60 cases of pulmonary tuberculosis. There is a marked increase in the notified cases of diphtheria.

An Irish Medical Man's Presence of Mind.

Mr. William Ormsby, while recently motoring from Ballina to Limerick, in attempting to pass a flock of sheep struck a low wall on the edge of a cliff some 50 or 60 feet above the underlying rocks. Just as the car was about to fall Mr. Ormsby jumped clear and escaped with a severe shaking.

Death of Mr. J. C. Woodside.

I regret to announce the death on June 29th, in the Royal Victoria Hospital, Belfast, after a lengthened illness, of Mr. J. C. Woodside of Ballycastle, co. Antrim, who was coroner for Ballymoney, and who for several years practised successfully in Ballycastle.

Sir George Plunkett O'Farrell, M.D.

The death of Sir George Plunkett O'Farrell on June 22nd, which was briefly announced in this column last week, has followed closely on his retirement from office as Lunacy Inspector in Ireland, as it was only in July of last year that he gave up this post. Sir George O'Farrell was the son of a medical man enjoying a good practice in Boyle, county Roscommon. He was educated at Trinity College, Dublin, where he won many distinctions, of which the chief were a moderatorship in natural science and the travelling studentship in medicine. Having finished his medical studies he joined his father in practice in his native town. In 1885 he was offered and accepted a medical inspectorship under the Local Government Board. Four years later he became Inspector of Reformatories and member of the General Prisons Board. This office he held for only a brief time, as in the following year he became one of the two Inspectors of Lunatics in Ireland. It was in this post that his most important public work was done. At the time of his appointment he was not an expert in insanity, and his lack of experience led to some difficulties in his intercourse with the more experienced heads of asylums. As time went by, however, O'Farrell became at home in his work, and his reports showed a thorough grip of the many problems arising in connexion with the care of the insane. It is not too much to say that much of the improvement in Irish asylums in the past 20 years is due to the wise advice and supervision of O'Farrell and his colleague, Dr. E. M. Courtenay. In particular they were active in removing the insane from workhouses to

asylums, a reform of great importance. They strove, too, for the betterment of the conditions of services of asylum attendants. In 1899 Dr. O'Farrell received the honour of knighthood. Last year, on his retirement from office, the officials of the Irish asylums joined in a presentation to Sir George O'Farrell in token of their appreciation of his work as Inspector of Lunatics.

The Water-supply of Belfast.

As is well known, all water undertakings are maintained by the amount of rainfall available in each during the six wet months—October to March, inclusive. The remaining six months—from April to September, inclusive—are known as the six dry months, during which very little water is available. Previous to the present extraordinary year, the lowest rainfall on record during the six wet months was from October to March, inclusive, of 1886–87, and amounted to 17·20 in. rainfall; the next driest was during the same wet months in 1892–93, when the amount of rainfall was 18·21 in.; while during the six wet months 1910–11 the rainfall was only 16·01 in., and this constitutes—as far as the Belfast water-supply is concerned—the lowest rainfall on record. But even since the end of March there has been very little rain, hence the Belfast Water Commissioners have wisely advised that all water consumers should exercise the greatest economy in the legitimate use of water for all purposes in order to avoid inconvenience at the end of the present summer.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Classical Studies in the Preliminary Course for Medicine.

THE medical syndicates are protesting vigorously against a decision announced last year by the Minister of Public Instruction. Up to now, in order to enter as a student in the Faculty of Medicine it has been necessary to obtain a special diploma, the certificate in physics, chemistry, and the natural sciences—commonly known as the P.C.N.—which is obtainable after a year's work in a university faculty of science. The possession of a Bachelor's diploma, however, was a pre-requisite to beginning these studies. Now there are four kinds of baccalaureate, according to the greater or less requirements respectively in Latin and Greek, the pure sciences, and living languages. The admission to the course for the P.C.N. as a step towards the study of medicine thus necessitated the acquirement of one or other of the three baccalaureates of which Latin and Greek form a component part; for the possessors of the fourth baccalaureate, obtainable on a curriculum of science and living languages, without Latin, Greek, or philosophy, and established for students on leaving the superior primary schools without any training in classical studies, were excluded. By a decree of April 16th, 1910, it was decided to admit the holders of this reduced baccalaureate to the course of the P.C.N., and consequently to throw open to them the medical curriculum, so that in future it will be no longer necessary to have undergone a classical course in order to enter on the study of medicine. This decision, prompted apparently by the political motive of throwing open to the proletariat the liberal professions, by removing the barrier hitherto interposed by the necessity for a preliminary classical education, has given rise to the most lively protests. The various medical societies of the Arrondissements of Paris, the Syndicate of Physicians of the Seine, and even the Association of Students in Medicine, have passed resolutions protesting against this decree, and demanding the restoration of Latin and Greek to a compulsory place in the medical curriculum. A communication on this point has been presented by Dr. Blondel to the Société d'Enseignement Supérieur, which has been widely republished by the lay press. It is insisted therein that a satisfactory course of medical studies cannot be constructed or a good medical practitioner trained except on the basis of a solid classical education. An acquaintance with Latin and Greek is indispensable for comprehending and retaining the terms of medical nomenclature, formed for the most part from one or other of these languages, and adopted bodily into the vocabularies of foreign tongues, thus facilitating at least a superficial comprehension by physicians of books and journals written in languages other than their own. It is further asserted that even the mentality of the medical man in relation to the practice of his art would suffer from the absence of a classical education. For the making of a diagnosis is accomplished by an intellectual operation which is in effect a hypothesis—that is to say, the medical man has to arrive at a conclusion from a part only of the elements of the problem. It is therefore necessary that his mind should have previously undergone a training in reasoning such as the philosophic studies alone can give. In practice the medical man of classical education is endowed, says Dr. Blondel, with faculties superior to those of his *confrères* not similarly favoured. His general culture, derived from familiarity with the ancient authors who have moulded the mental faculties of all preceding European generations, is certainly superior; and for the developing in him of the qualities of tact, discriminating compassion, and solace to those who suffer, nothing can replace them. The well-known surgeon, Dr. Labbé, president of the Academy of Medicine, and Senator, will lay before the Senate a *résumé* of the views of the medical syndicates and the medical press, and will call upon the Minister to restore the former condition of things.

The Services of Public Assistance.

M. Mirman, Director of Public Assistance and Hygiene, has presented to the Conseil Supérieur de l'Assistance a report covering his entire services. The labours in puericulture, maternal assistance, and the protection of children of tender age have lowered the infant mortality below one year. The mean yearly death-rate in communities with a population of more than 5000 inhabitants was 258 from 1892–95; 229 from 1896–1900; and 164 from 1901–05. In 1906, 145 died; in 1907, 129; in 1908, 129; and in 1909, 117. The number of people receiving gratuitous medical aid increases constantly. The total of those so assisted, either in their own homes or in hospitals, which in 1905 amounted to 615,872, rose in 1909 to 996,539 by a continuous and almost regular increase of 27,000 per annum. The increase in expense mounts by an even more violent progression. Starting at 3,696,000 francs in 1895, it attained in 1909 the figure of 18,416,000 francs. Under the law of 1905 for the assistance of the aged, the infirm, and the incurables, the number of beneficiaries does not cease to increase, though the rate of increase is receding, for since the third quarter of 1908 this figure, which was then 515,480, has increased in succeeding quarters by 25,000, then 7000, and 6000, until at the end of the first quarter of 1911 the increase was only 77. The annual expense of the administration of the law of 1905 is about 100,000 francs.

The Transformation of the Hôtel Dieu.

The Public Assistance proposes to devote to the work of transforming the Hôtel Dieu a part of the funds that have been allotted to it out of the municipal loan of 900,000,000 francs. The chief feature of the plan consists in the installation of a maternity department, of which the Hôtel Dieu has been deprived since the demolishing of the annex in the Rue de la Bucherie. The new maternity will be situated in the eastern portion of the buildings overlooking the Quai aux Fleurs. The plan contemplates also a consolidating of the ophthalmologic services at present disseminated through the hospital, as well as the construction of a new linen department and of two operating rooms furnished with modern apparatus and instruments, and equipped according to the desiderata laid down by the surgical staff. The greater part of the other services will be reinstalled under better conditions, and a radiographic service will be established, so as to allow the patients to be examined at the Hôtel Dieu itself, instead of their being sent to the central radiographic service at the Salpêtrière. Finally, the Hôtel Dieu will be fitted throughout with electric light and steam heat. The estimated expense will be about 1,810,000 francs. The plan prepared by the Administration of Public Assistance will doubtless come before the Municipal Council during its present session.

July 3rd.

NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.—The Princess Christian's Farm Colony will be opened by H.R.H. Princess Christian of Schleswig-Holstein on Tuesday next, July 11th, at 3.30 P.M., at Hildenborough, Kent.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Question of a Statutory Compulsion of Medical Practitioners to Attend Patients.

AT a recent meeting of the Parliamentary Committee which is considering the Bill for the suppression of medical practice by unqualified persons some members moved that qualified medical men should be liable to punishment if they declined to attend patients who sought their advice, exceptions being admitted only under the law. The supporters of this view said that if this Bill became law qualified medical men would have a monopoly of treating certain diseases to the complete exclusion of unqualified persons, and this being so they must not be allowed to decline attendance on patients desirous of consulting them, as otherwise great inconvenience may arise for the public. The Secretary of State replied that statutory provisions in this sense had existed until about the year 1867; they could not be re-enacted now, and would, moreover, be quite useless at the present time, when qualified medical men were so numerous and competed with one another so that the public was nowhere without opportunities of obtaining proper medical attendance. He stated that he had no knowledge of the existence in any country of such compulsion of medical men to attend every patient, but he would request the medical chambers to communicate with him on the subject. This proposal has caused great indignation throughout the profession, although it is very unlikely that it will be adopted. The editor of the *Zeitschrift für Ärztliche Fortbildung*, a journal for post-graduate study, has made inquiries for the purpose of ascertaining whether anything of the nature of such compulsory attendance exists in foreign countries, and the results of that investigation, which included the United States of America, Belgium, Denmark, Great Britain, France, the Netherlands, Norway, Austria, Russia, Sweden, Switzerland, and Hungary, were published in a recent issue of that journal. It was stated that a similar provision exists in only one of the above-mentioned countries—namely, in Russia. According to the Russian law a medical man is obliged to see a patient in the latter's residence when asked to do so, and this obligation is specially binding when he is requested by a midwife to attend a confinement; the fines for failure to comply with the law are 10 roubles (about £1) for the first contravention, 50 roubles for the second, and 100 roubles for the third. In the case of a confinement the medical man is even liable to punishment if he leaves the woman before the end of the labour. No other country has such draconic legislation, but in certain countries, as, for instance, in Sweden and in Norway, the governmental and municipal medical officer must attend patients when requested to do so; in Switzerland and in Hungary there is a statutory obligation on medical practitioners to give first aid to injured persons and to those who are taken suddenly ill; but in the majority of the countries there is no law at all of that kind. The answer received from France in reply to the query was very characteristic, being to the effect that medical practitioners in that country were not under any compulsion to attend patients even in urgent cases; the question was one of humanity, and it has not yet been found necessary to enact laws compelling the medical profession to be humane. Undoubtedly the medical chambers will give a unanimous opinion adverse to the proposed innovation, but the incident makes it obvious that the Bill in question has many Parliamentary opponents who are doing their utmost to hinder its adoption.

The Wassermann Reaction in Lead Poisoning.

Dr. Dreyer of Cologne, writing to the *Deutsche Medizinische Wochenschrift*, states that he has obtained a positive Wassermann reaction in certain cases of lead poisoning. Of 35 cases examined, 4 showed the reaction, although the men had never been syphilitic. In 25 of them the sera were, moreover, examined according to Stern's modified method, the result being that a positive reaction was obtained in 12 cases. Dr. Dreyer considers that the lead poisoning itself and not the anæmia of the patients was very likely the cause of the reaction being positive, as it was always negative in cases of anæmia from other causes. He has further investigated the question whether poisoning by other metals has the same effect; he found that three cases of chronic mercurial poisoning in men employed in factories where mercury was much used had an absolutely negative reaction. Dr. Dreyer's statements are confirmed by Dr. Schnitter of Offenbach, who examined the blood serum of 16 workmen presenting symptoms of lead poisoning; 4 of the men showed a positive reaction; 1 of them had suffered from syphilis three years ago, although no symptoms of the disease existed at the time of the examination. It was worthy of notice that in the blood of the cases giving a positive reaction a great quantity of basophilic erythrocytes was present. The men giving a positive reaction had been engaged in the lead work for various periods from 18 to 40 weeks, and the others for periods from two days to seven weeks; it was therefore probable that the positive reaction in lead poisoning depends on the degree and the duration of the poisoning.

July 3rd.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

South African Memorial to King Edward.

IN order to test the general feeling of the South African public on the question of the form to be taken by a memorial to King Edward, the committee, instituted as described in THE LANCET of Feb. 4th, addressed communications to the different local and health authorities and to the medical societies throughout the Union, inquiring whether they were in favour of an order of nurses, of the establishment of sanatoriums, or of any other plan of a similar character equally appropriate as a memorial and more likely to be acceptable to South Africa as a whole. The replies received, which were almost without exception cordially in support of the movement, favour in the proportion of 4 to 1 the establishment of an order of nurses—the Viscountess Gladstone's own proposal—in preference to sanatoriums. The larger towns were mostly in favour of sanatoriums, but in these the need for trained nursing assistance is not so pressing as in up-country villages, owing to the fact that the former are mostly provided with hospitals. The smaller towns were unanimous in favour of the nursing scheme, while the medical societies were fairly evenly divided on the two proposals. An appeal has just been made by the committee for a minimum capital sum of £100,000, which it is estimated will be required to place the nursing scheme on a sound footing.

The New Order of Nurses.

It is proposed that branches of the new Order of Nurses should be established at appropriate centres in each province, selected with particular regard to facility of railway communication. Each branch is to be under the supervision of a matron. The nurses will be required to possess such certificates in general nursing and midwifery as are requisite for registration in any part of the Union, and to have as far as possible experience of South African conditions. They will receive fixed salaries, the money received from fees being paid by the matron into the central fund. Except in urgent cases the services of the nurses will be available only on requisition by a medical man, on whose certificate and subject to instructions from the central committee, the matron will decide whether full fees are to be charged or whether part or total remissions shall be made. The expenses of the order will be met in part from fees and in part from donations and subscriptions. As the needs of the Europeans and the natives are distinct, it is proposed that the contributions of the coloured and native population should be devoted to the training of coloured and native nurses at Lovedale and similar institutions, and in order to give effect to this that the contributions from the coloured and native population to the memorial should be kept distinct. In an otherwise excellent scheme this appears to be likely to prove unsatisfactory, for the difficulty is at present for the few coloured or native trained nurses in South Africa to obtain work, and to increase the number of these nurses without finding them situations will not be of much benefit. It would probably have been better to provide for the funds to be utilised in employing salaried and native nurses at centres where there

are large coloured and native populations, but if the appeal is successful this will doubtless be done. It is to be trusted that Lady Gladstone's endeavours will be successful and that her appeal to the generosity of South Africans will not be made in vain. The Association for the Prevention of Tuberculosis, an association established some years ago in Cape Town, has tried in recent years as a main objective to induce the Government to establish a number of sanatoriums; and apparently when the memorial committee was sounding the public as to the form of proposed memorial its council took steps to impress upon the committee its views. The public, as already stated, were against this proposal, and the committee had no option but to reject it accordingly. Some of the council, including the Mayor of Cape Town, however, have handed in their resignations in indignation at what is held generally to have been an unwarrented protest.

Prevalence of Tuberculosis.

The memorial committee has considered very carefully the question of the memorial taking the form of sanatoriums, and published a letter addressed by it to the Prime Minister on the subject. In this letter it was stated that in the course of its inquiry the committee had been deeply impressed by the evidence from all parts of the Union of the need of some provision for the treatment and prevention of consumption, and that it desired to direct his attention to the magnitude of the evil and the state of public feeling on it. In commending it to the attention of the Government, the committee expressed the earnest hope that the Government might find it possible to take measures without delay to remedy what is indisputably a serious danger in the future of South Africa. The tuberculosis menace has been strenuously impressed upon the Government recently from other directions. The recent Medical Congress passed the following resolution on the subject:—

That this Congress, recognising the serious prevalence of tuberculosis among the European and coloured races of this country, and the inadequacy of the present means of coping with the disease, respectfully requests the Government to appoint a Commission to investigate the amount of tuberculosis among the white and coloured races of the Union, what steps are being taken in the different Provinces to deal with the disease, and what provisions exist for research and for the treatment of tuberculosis according to the best methods known to modern science.

A few weeks ago a deputation from the Standing Committee of Congress waited upon the Minister for the Interior to present this and other resolutions. General Smuts informed the deputation that he thought a Commission might perhaps serve a useful purpose and that the Government would give the matter due consideration. Recently, also, a joint deputation from the Association for the Prevention of Tuberculosis and the Western branch of the British Medical Association waited upon the Cape Administrator with a view to urging upon the Government of that province the necessity of providing adequate hospital accommodation for consumptives. The Administrator explained that the providing of sanatoriums might be considered a public health measure, and, if so, the Provincial Government could not very well do anything in the matter without the sanction of the Union Government. He, however, stated that as hospitals were under the provincial governments it was possible sanatoriums might also be held to be under the local administrations, in which case he would bear their representations in mind. He explained that a new chronic sick hospital was shortly to be erected in the vicinity of Cape Town, and said that he proposed to ask the Provincial Council to sanction expenditure for a special consumptive block to be used for cases that were beyond hope of recovery and which if left in their homes were considered to be a menace to the public. The subject of tuberculosis was also recently discussed in the Cape Provincial Council, when on the motion of Dr. B. Hewat, Member for Cape Town, a select committee was appointed to consider the matter. The select committee, however, after taking some evidence, is understood to have brought up merely an interim report recommending that it should be reappointed the following session. It is understood that in view of the pressure that has been brought to bear on Ministers the Government is seriously considering the appointment of a commission to go into the whole question. It is not quite easy to realise what there really is for a commission to investigate, for no new facts or figures are likely to be elicited. But, of course, the recommendations of a commission would carry weight, particularly if its members were medical experts. If such a commission is appointed no doubt the Standing Committee of Congress and the various medical societies in South Africa will take action to ensure that the views of the profession in South Africa are represented to the Commissioners, and that the Commissioners impress upon the Government that this national danger cannot be adequately dealt with except under the guidance of a properly organised health department under its own expert head. Dr. P. Murison, medical officer of health of Durban, has induced the council of that town to appoint an experienced medical officer to work under his direction in connexion with a municipal dispensary that is to be opened in Durban for the treatment of any tuberculous pauper requiring medical treatment. Care is to be taken to prevent the possibility of abuse of the dispensary. The medical officer who has been appointed will, it is understood, also be available to assist Dr. Murison in other directions, but he is expected to concentrate mainly on the tuberculosis problem. The experiment will be watched with interest by workers in public health in South Africa, and if it appears to be a success doubtless an effort will be made to induce some of the other large municipalities to follow the example of Durban.

June 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Administrative Control of Consumption.

THE complete list of recommendations made by the recent conference of heads of State public health departments for the administrative control of consumption was published on May 6th. The most novel were the following:—

12. Legal power should be given to examine medically contacts of consumptive patient.

18. Legal power should be given to the central health authority to regulate the conditions in which home-dwelling consumptives live. The object of notification being the control of the consumptive as a possible disseminator of infection, there should be power not merely to visit his and inquire into the circumstances in which he lives, not merely to advise him what he should do for the safety of others, but power to direct him to take the few and simple precautions which are necessary to safeguard his housemates. The penalty for persistent disobedience, the consequence of the physical impossibility of taking these simple precautions, is but one, and is mentioned in the next resolution.

19. Legal power should be given to the central health authority to remove dangerous consumptives into segregation on the order of police magistrate given after private hearing on application of the central health authority. This is but a corollary to the preceding resolution. It would very rarely be necessary to exercise this power but possession of it is indispensable. It would be applied (*a*) to the small number of persons who persistently decline to take the precautions enjoined upon them for the safety of others; (*b*) to the somewhat larger number of persons whose circumstances, either of poverty or of advanced illness combined with small means, render observance of the necessary precautions by them physically impossible. This form of control should be applicable not merely to persons in dwelling institutions, and the like places, but also to those frequenting work shops and places of public resort.

20. The duration of the legal detention of persons compulsorily segregated should be determined only by order of the court on recommendation of the central health authority, any patient to have the right to apply for release. Any permit of release must be obtained on application to the court.

These proposals were at once adversely criticised and it is unlikely they will be proposed in the House.

Imperial University Congress.

The Senate of the Sydney University has nominated Sir Beauchamp (formerly Governor of New South Wales), Professor Anderson Stuart, Professor Warren, Dean of the Faculty of Engineering, and Mr. Burff, Registrar of the University, as delegates to the Imperial University Congress.

New South Wales Country Hospitals.

A deputation of medical men have waited on the acting Chief Secretary to protest against the following circular with regard to the appointment of honorary medical officers to subsidised hospitals outside the metropolis:—

A place on the medical staff shall be open to every reputable practitioner of the district who desires to occupy one, the roster to be settled by the committee after consultation with the medical men who have been appointed on their application, all appointments to be effected the title of "honorary surgeon" to be abolished as a distinct designation, but retained if preferred on condition it applies to members of the medical staff alike.

The payment of Government grants was made conditional the acceptance of this proposal. The main objection of deputation was that no choice was left to the controll

bodies of hospitals, and that in small hospitals a chaotic condition would ensue if the staff was over-manned. The Chief Secretary promised that the matter would be reconsidered, but stated it had been adopted on the advice of the chief medical officer to the Government.

Royal Prince Alfred Hospital, Sydney.

The twenty-seventh annual meeting of this institution was held in Sydney on April 26th. The strain on the hospital resources had been greater during the past year than at any previous period, the daily average of occupied beds being 372. Operations totalled 3901. Professor Anderson Stuart, who was in the chair, stated that the financial position was unsatisfactory, and that the debit balance would be increased unless Government assistance was forthcoming. Unless some relief were obtained it would be necessary to consider reducing the number of beds, a step the committee were loth to take. The expenditure was £28,764.

The Use of Hospital Funds.

The Acting Premier of Victoria has criticised adversely the action of the Melbourne Alfred Hospital authorities in devoting £50 from the general hospital revenue to the payment of portion of salary of a clinical pathologist. One of the physicians to the hospital has replied in the daily press that such a position must be filled in the interests of the patients and hospital at the same time.

Care of Children.

The report of a committee appointed by the Child-saving Council of Melbourne strongly urges that the boarding-out system should be extended. The committee were struck with the irresponsive demeanour of institutional children as compared with those in the care of foster parents. Institutions should be limited as far as possible to: (1) receiving homes; (2) homes for wayward children; (3) homes for mentally defective children; and (4) for those requiring technical training. There was evidence of overlapping among existing institutions. All homes should be subject to regular medical inspection. Surprise was expressed that so few of the homes maintained trained nurses on the staff.

The Richmond Railway Accident.

The Minister for Railways for Victoria has handed to the press a list of the medical men who were paid by the department for their attendance on sufferers in the Richmond railway accident which occurred in July, 1910, and resulted in alleged injury to some 480 persons. The total amount paid in medical fees was £16,699 13*s.* 6*d.*, besides £982 for private hospital accommodation. The individual amounts varied from £2 2*s.* to £1984. It has been generally felt that some better system will have to be put in force in the future. Although such a list makes no mention of the actual work done, in many cases the fees charged appeared excessive in amount. It is not intended to convey that this is brought about except by a needless number of visits being entered against the department. It is calculated that on a basis of 10*s.* per visit over 32,000 visits were paid for.

Health of Miners.

A Royal Commission has been appointed by the Queensland Government, consisting of Mr. Murphy, M.L.A., Mr. Jackson, M.C.E., and Dr. J. S. C. Elkington, to inquire into the health and conditions of work of miners in various parts of Queensland. The incidence of pulmonary diseases and the regulation of employment of persons suffering from tuberculosis as miners are to form part of the inquiry.

New Brisbane Hospital.

The Mater Misericordiæ Hospital, which has been established in Brisbane by a nursing sisterhood of the Roman Catholic Church, is now open for patients, and appears to be very complete as regards building and equipment. The honorary staff as at present constituted comprises four surgeons, four physicians, and there are special departments for dermatology, ophthalmology, pathology, and dentistry.

Obituary.

The death of Alexander Lawrence, M.D. Edin., L.R.C.S. Edin., is announced from Adelaide, in which city he practised for many years past. The late Dr. Lawrence was a native of Brechin, Forfar. He had an intimate acquaintance with small-pox and was frequently consulted as an expert in quarantine cases. He originally came to South Australia on account of his health, having been in practice in the old country. Personally, he was very popular and enjoyed the confidence of a large circle of patients. He leaves one son and daughter, the latter having married Dr. Lionel Hayward some years ago.

June 5th.

Medical News.

UNIVERSITY OF OXFORD.—The following candidates have been approved in the undermentioned examinations:—

FIRST B.M.

Organic Chemistry.—H. E. Bamber, J. N. L. Blarney, L. G. Burford, A. Jackson, T. L. Price, J. A. G. Sparrow, and A. Traill.

Human Anatomy and Physiology.—H. E. A. Boldero, L. G. Brown, F. B. Chavas e, W. T. Collier, V. T. Ellwood, R. C. Fairbairn, R. J. Inman, M. R. Laurence, G. A. Maling, T. S. Nelson, O. B. Pratt, G. S. Robinson, C. P. Sells, J. A. G. Sparrow, N. A. Sprott, C. P. Symonds, and H. A. B. Whitelocke.

SECOND B.M.

Medica Materia and Pharmacology.—W. J. Hart, H. M. Pope, E. Scott, and J. A. Wood.

Pathology.—J. L. Birley, A. Booth, C. H. Budd, A. A. M. Davies, H. T. Evans, R. A. Faucus, J. R. Kay-Monat, D. P. M'Donald, W. H. Ogilvie, R. C. Ozanne, H. M. Pope, J. Sainsbury, W. W. Wagstaffe, and R. O. Ward.

Forensic Medicine and Public Health.—H. C. Bazett, J. L. Birley, A. Booth, N. S Lucas, H. W. Scott-Wilson, P. T. Spencer-Phillips, C. J. G. Taylor, W. W. Wagstaffe, and W. C. Wigan.

Medicine, Surgery, and Midwifery.—H. C. Bazett, A. R. Chavasse H. J. B. Fry, A. D. Gardner, J. A. Noble, E. R. Pearce-Gould J. F. Penson, P. T. Spencer-Phillips, and W. W. Wagstaffe.

The following degree has been conferred:—

D.M.—Charles Singer.

UNIVERSITY OF LEEDS.—At a Congregation of the University held on June 30th the following pass lists were issued:—

SECOND M.B., CH.B. EXAMINATION.

Part I.—C. M. Gozney, E. Hesterlow, W. D. A. King, and J. Wright

Part II.—W. D. Anderton, R. H. Chadwick, D. A. P. Clarke, S. N. Cohen, J. J. Digges la Touche, H. Foxton, A. S. Hebblethwaite, E. Hesterlow, F. King, W. D. A. King, H. S. Lockwood, K. Menon, H. W. Robinson, C. H. Seville, H. Shochet, J. Wilkinson, and C. Wilson.

FINAL M.B., CH.B. EXAMINATION.

Part I.—H. Angel, J. H. Blackburn, T. Elliott, J. Ferguson, G. W. L. Kirk, G. P. Mellis, J. C. Metcalfe, N. V. Mitton, M. Peto, S. Samuel, and H. W. Symons.

Part II.—C. S. Brown, J. B. Fisher, A. Riley, and T. L. Walker. Mr. Fisher has been awarded first-class honours.

Diploma in Public Health.—C. N. Smith.

Diploma in Dental Surgery (First Professional Examination).—H. V. Waddington.

ROYAL SOCIETY OF ARTS.—The annual general meeting of the Royal Society of Arts took place recently, Sir John Cameron Lamb, C.B., C.M.G., chairman of the council, presiding. The annual report shows that the office of president has now been accepted by H.R.H. the Duke of Connaught. Up to the death of King Edward VII. it was occupied by H.R.H. the Prince of Wales (King George V.), and, on his accession to the throne, it was temporarily held by the Lord Chief Justice. During the year 22 papers were read at the ordinary meetings of the society, six in the Indian, and five in the colonial section. There has been, as usual, an increase in the entries for the society's examination, the total number of papers worked this year being 34,260. Under the Fothergill Trust, as has been announced in THE LANCET, the council has made the following awards for life-saving apparatus for use in mines and places where the air is noxious: gold medals to Mr. H. A. Fleuss and Mr. W. E. Garforth, and silver medals to Mr. Richard Jacobson and the Mining Engineering Company. The society's Albert medal has been awarded to the Hon. Sir Charles A. Parsons, K.C.B., F.R.S., for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type. The council has awarded silver medals

for papers read during the past session to Dr. Leonard Hill for his paper on "Caisson Sickness and Compressed Air," and to Mr. James Cantlie for his paper on "Plague."

THE MIDWIVES ACT, 1902.—It is officially notified in the *London Gazette* that the Privy Council has approved of revised rules, for the period of five years commencing on July 1st, submitted to it by the Central Midwives Board.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY'S GOLD MEDAL.—The gold medal of this society, which in awarded every three years for distinguished work is medical science, was presented to Professor A. Neisser on June 27th at the Kensington Town-hall, after he had delivered the Cavendish Lecture.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on June 16th. There were present Dr. F. de Havilland Hall (in the chair), Dr. St. Clair B. Shadwell, Dr. F. C. Martley, Dr. F. S. Palmer, Dr. J. Pickett, Dr. H. A. Sansom, Mr. J. Brindley-James, Mr. H. P. Symonds, Dr. R. Hutchison, Dr. F. J. Allan, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The business of the society during the last few months has been very satisfactory. Although fairly numerous, the sickness claims have been for the most part of short duration, and the total sickness pay disbursed has been well under the amount expected and provided for in the rates of contribution. With the view of mitigating the hardships of some of the cases of distress which come under the notice of the committee it was resolved to subscribe 100 guineas a year to the British Medical Benevolent Fund. The funds of the Medical Sickness and Accident Society cannot be directly used for charitable purposes, but the committee trusts that this subscription will enable it in some cases to be of use to members of the society in temporary distress. Prospectuses and all further information may be had on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of this association was held at the Holborn Restaurant on June 15th, Dr. Rashell T. Davison being in the chair. Mr. D. A. Belilios, the honorary secretary, reported that the following associations and societies had appointed delegates to the Joint Permanent Committee of General Practitioners who hold public appointments under central or local bodies: Poor-law Medical Officers, Public Vaccinators, Postal Medical Officers, Metropolitan Police Surgeons, Certifying Factory Surgeons, and the Association of Medical Officers of Health. The council appointed Dr. Rashell Davison, Dr. F. G. Crookshank, and Mr. Belilios to represent the association.—A meeting of the Joint Permanent Committee of Medical Officers was held later, when the temporary honorary secretary reported that the following representatives had been appointed by the respective bodies: Dr. A. E. Cope, Mr. V. A. Jaynes, and Mr. G. W. Brabyn by the Public Vaccinators; Dr. C. Owen Fowler, Dr. G. Nicol Henry, and Dr. A. Dumville Roe by the Metropolitan Police Surgeons; Dr. J. H. Keay, Dr. W. A. Atkinson, and Mr. W. H. F. Oxley by the Certifying Factory Surgeons; Dr. Major Greenwood, Mr. A. Withers Green, and Mr. T. L. Brown by the Poor-law Medical Officers; Dr. R. R. Giddings, Dr. John Matheson, and Dr. George A. Mason by the Postal Medical Officers; and Dr. Crookshank, Dr. Rashell Davison, and Mr. Belilios by the Association of Medical Officers of Health. Dr. Rashell Davison was elected to the chair, and he proposed that Mr. Henry Bott of Brentford be asked to be the chairman of the committee for the ensuing year. This was seconded by Dr. Giddings and carried unanimously. It was proposed by Dr. Mathieson, seconded by Dr. Mason, and carried, that Mr. Belilios be appointed honorary secretary and treasurer. The proposed rules of the committee were discussed and passed. A resolution was unanimously carried that the objects were to conserve the interests of all medical practitioners who hold appointments under local and central authorities. The medical provisions of the National Insurance Bill were discussed, and it was unanimously agreed that in order to preserve an unbroken line the policy of the British Medical Association as outlined in its recent circular to the profession be supported. It was further decided to bring to the notice of the British Medical Association the clause (Clause I., Part II., Schedule IV.) of the Bill which contemplates bringing women and children into medical benefit when funds become available. It was recommended that the clause be deleted. Mr. Withers Green proposed and Mr Brown seconded—

That the medical representation on the Local Health Committee and the Advisory Committee equals at least the representation of the Friendly Societies and Post Office contributors combined. The local profession in each district to elect representatives on these committees

It was pointed out that while the profession was unanimous in its insistence to be freed from the control of the Friendly Societies, it was not by any means clear that the control of the medical practitioners by a Local Health Committee would be any improvement unless the term "adequate" representation of the profession be defined in the Bill itself. It might mean the case of falling from the frying-pan into the fire. A vote of thanks to Dr. Rashell Davison was carried by acclamation.

THE FIFTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—The Fifteenth International Congress on Hygiene and Demography will be held in Washington, D.C., from Sept. 23rd to 28th, 1912, under the honorary presidency of the President of the United States. Dr. Henry P. Walcott, President of the State Board of Health of Massachusetts, will be the active president. Twenty-two Governments have already accepted the invitation to participate, issued by the Government of the United States, and in addition each of the States of the Union which for health purposes is an independent self-governing body, has received an invitation which includes its cantons and cities. The committee on organisation created by the U.S. Department of State consists of 53 members, and includes Dr. Hermann Biggs, Dr. John S. Billings, Professor R. H. Chittenden, Professor Irving Fisher, Colonel Gorgas, Professor Theobald Smith, Surgeon-General Sternberg, Professor W. H. Welch, and Surgeon-General Wyman, with other well-known medical men, sanitarians, and social economists. The secretary-general is Dr. John S. Fulton, Army Medical Museum, Washington, D.C. The official languages will be English, French, and German. The work of the Congress falls into two branches: first, an exhibition of the recent progress and of the present condition of the public health movement in the coöperating countries; secondly, the scientific meetings, for which purpose the Congress will be divided into the following nine sections each of which will meet daily and may propose resolutions regarding matters of practice or lines of desirable investigation. These resolutions will come before the closing session of the Congress. The sections are:—I. Hygienic Microbiography and Parasitology—President: Professor Theobald Smith, Harvard Medical School, Boston. II. Dietetic Hygiene, Hygienic Physiology—President: Dr. Russell H. Chittenden, Yale University, New Haven, Conn. III. Hygiene of Infancy and Childhood and School Hygiene—President: Dr. Abraham Jacobi, College of Physicians and Surgeons, New York. IV. Industrial and Occupational Hygiene—President: Dr. G. M. Kober, Georgetown University, Washington, D.C. V. Control of Infectious Diseases—President: Dr. Hermann Biggs, Department of Health, New York. VI. State and Municipal Hygiene—President: Dr. Frank F. Wesbrook, University of Minnesota, Minneapolis. VII. Hygiene of Traffic and Transportation—President: Dr. W. Wyman, U.S. Public Health and Marine Hospital Service, Washington, D.C. VIII. Military, Naval and Tropical Hygiene—President: Dr. H. G. Beyer, Medical Director, U.S. Navy, Washington, D.C. IX. Demography—President: Professor Walter J. Willcox, Cornell University, Ithaca, N.Y. Notice of a desire to present a paper or demonstration should be sent to the president of the appropriate section, enclosing an abstract of the paper. Each member will receive a report of the Transactions and of the Protocol to be published after the adjournment of the Congress. Membership in the Congress is open to those interested in public health or vital statistics, on payment of the membership fee of $5 (about £1). Inquiries and applications for membership should be addressed to the Secretary-General of the Fifteenth International Congress on Hygiene and Demography, Army Medical Museum, Washington, D.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Medical Men and the National Insurance Bill.

WHEN Parliament reassembled after the Coronation festivities the negotiations between the Chancellor of the Exchequer and a special committee of the British Medical Association were resumed as to the position of medical men under the National Insurance Bill. The interval that has elapsed since the measure was introduced has revealed the united opposition of the profession to the terms which its members were offered, and in meeting Mr. LLOYD GEORGE the medical representatives had precise and definite demands to make. It is essential to the scheme of the Bill that the coöperation of medical men should be enlisted. There is every reason to believe that the Chancellor of the Exchequer was alive to this aspect of the situation when the negotiations were resumed, and was anxious, if possible, to secure an understanding with the medical profession before the House of Commons began the consideration of the Bill in Committee; in fact, it has been part of his general policy on the Bill as far as possible to adjust differences with various interests affected by it before Parliament sets to work on the details. Negotiations on these matters, however, are delicate and sometimes difficult. Those with the representatives of the medical profession have been conducted in private. On June 29th it was unofficially stated that a tentative agreement on several points at issue had been reached. According to this statement the Chancellor of the Exchequer had conceded free choice of medical men by insured persons and medical representation on the bodies which are to administer the Bill when it becomes law. It was further stated that the question of Friendly Society control might by consent be left to the House of Commons. The question of the income limit, which it is contended should confine the benefits of medical attendance and treatment to the less highly remunerated classes of the community, seems to have proved a very serious obstacle in the way of agreement. It is understood that the medical representatives and Mr. LLOYD GEORGE discussed the matter at length on Friday, but no settlement was reached. However, the negotiations were postponed until this week.

The PRIME MINISTER in the afternoon of Wednesday relieved general apprehension by moving that the proceedings on the National Insurance Bill, if under discussion at 11 P.M., should not be interrupted under the Standing Order.

Mr. LLOYD GEORGE, in the course of a speech on the National Insurance Bill in the House of Commons on Wednesday afternoon, let fall the remark, "substantially the opposition of the doctors has been met." The Chancellor of the Exchequer has been in negotiation with the representatives of the medical profession, and at the beginning of this week the important point of the income limit remained to be dealt with. Inquiry in a responsible quarter elicits the information that Mr. LLOYD GEORGE is now giving close consideration to the precise terms of a scheme which is designed to replace the provisions of the Bill in so far as the question of medical benefit and income-limit is involved. The representatives of the medical profession were immovably opposed to any plan under which persons who could reasonably be expected to pay fees should obtain medical attendance on the terms which the Bill gives to insured persons. It is understood that the Chancellor of the Exchequer has recognised the force of these contentions. The precise detailed terms of the new scheme have not transpired. However, it is understood that it is to proceed on the principle that persons who can pay fees to medical men for attendance but who would claim medical benefit under the National Insurance Bill are to continue to pay fees, but their medical benefits are to be accumulated. When illness comes these accumulated benefits will be set towards paying the medical man, and after they are exhausted the patient will pay from his own resources. A concrete case will illustrate the working of the scheme. A person who is in a position to pay medical fees becomes an insured person and his medical benefit is calculated at, say, 7*s.* per annum. He has no illness for five years. At the end of that period he has to call in a medical man. 35*s.* of medical benefit have accumulated to the credit of this patient and may be expended on paying for medical attendance on him before he has to fall back on his own resources. That is the general idea which is understood underlies the scheme to which Mr. LLOYD GEORGE is giving his mind.

It is understood that the amendments to carry out any arrangements which come to with the medical profession on the National Insurance Bill will, when adjusted, be placed on the notice paper by the Chancellor of the Exchequer. There will be one exception. The amendment to give the control to the Health Committees will be brought forward by a private Member.

Medical Men and the House of Commons.

Medical men have taken ample care that their claims for fair treatment under the National Insurance Bill shall be impressed on the minds of Members of Parliament. The committees and organisations in the country have been active both by lobbying at Westminster and by letter in bringing to the notice of Members the points in the measure which will operate with hardship on the profession. Undoubtedly the resolute front taken up in the country by medical men towards the Bill has produced a notable impression at Westminster, as it is recognised that their united hostility to the measure would strike a most serious blow at its usefulness.

Amendments to National Insurance Bill.

A very large number of amendments to the National Insurance Bill have been tabled. Dr. HILLIER has given notice of a series to Clause 14 (administration of medical benefit). The effect of these would be to give to the Local Health Committees the duty of making arrangements with medical practitioners for insured persons to receive attendance and treatment. By this proposal the Local Health Committees would entirely supersede the approved societies for this purpose.

Dr. HILLIER further proposes that for the purposes of this medical treatment the Health Committee shall—

"(*a*) prepare and keep a list of registered medical practitioners who have entered into arrangements with the committee for giving medical treatment and attendance to insured persons entitled to medical benefit;

"(*b*) include in the list every registered medical practitioner practising within the county or the county borough who applies to be included, unless in respect of any such practitioner the Insurance Commissioners are satisfied, after due inquiry, that his appointment would be prejudicial to the efficiency of the service, and the Insurance Commissioners may, on due inquiry and after notice to the registered medical practitioner concerned, remove from the list of registered medical practitioners for any county or county borough any medical practitioner whose conduct is prejudicial to the efficiency of the medical service or insured persons."

Dr. HILLIER also brings forward an amendment to this effect:—

"Every insured person entitled to medical benefits shall be entitled to select from the list of medical practitioners kept by the Local Health Committee a medical practitioner, and unless that medical practitioner forthwith after receiving notice of the desire of an insured person to be attended by him notifies in writing the Local Health Committee and the insured person concerned that he is unwilling to comply with the desire of the insured person it shall be the duty of that medical practitioner to attend the insured person under this part of this Act."

The honourable Member also proposes that words shall be introduced into Clause 41 to provide that amongst the Insurance Commissioners "the medical profession shall be adequately represented." He also asks that on the Advisory Committee there shall be representatives of "registered medical practitioners who have had personal experience of general practice amongst the classes from which the insured are drawn."

Sir PHILIP MAGNUS has placed upon the notice paper amendments identical to those put forward by Dr. HILLIER.

Mr. NEEDHAM has given notice of an amendment to Clause 14 similar to one which already stands on the paper. Its terms are as follows:—

"(1) All arrangements of the Local Health Committee with medical practitioners for attendance and treatment of insured persons shall be subject to the approval of the Insurance Commissioners.

(2) The Local Health Committee shall prepare a list of registered medical practitioners who have entered into arrangements with the committee for giving attendance and treatment to insured persons whose medical benefit is administered by the committee.

(3) In the list of registered medical practitioners from whom insured persons shall make their selection the Local Health Committee shall include all registered medical practitioners who apply to be included, unless in respect of any such practititioner the Insurance Commissioners are satisfied after due inquiry that his appointment would be prejudicial to the efficiency of the service.

(4) The Insurance Commissioners shall have power at any time after due inquiry to remove from the list of registered medical practitioners for any district any practitioner whose conduct is deemed by them to be prejudicial to the efficiency of the medical service of the insured.

(5) Every insured person shall be entitled to select from the list so prepared a medical practitioner, subject to the consent of such practitioner, to attend him when required."

An amendment to Clause 8 standing in the name of the Earl of RONALDSHAY is designed to meet the demand of the medical profession that no insured person shall be entitled to medical benefit who is in receipt of an average income from all sources exceeding £2 per week.

Mr. ROWNTREE, in an amendment to the same clause, proposes that "medical benefit" shall include "such medical and surgical appliances as may be prescribed by the regulations to be made by the Insurance Commissioners."

A series of amendments relating to "maternity benefit" stand in the name of Mr. BEALE. One of these provides that in the administration of this benefit under Clause 16 the conditions "shall, as far as possible, leave to the mother the choice of being attended by a registered

medical practitioner or a duly certified midwife, and the selection of the medical practitioner or midwife from among those who according to the conditions shall be available." Another of Mr. BEALE'S amendments proposes that "maternity benefit shall not deprive the mother of the child from medical benefit so far as regards the attendance of a medical practitioner when such attendance is called in by a midwife in accordance with rules governing her practice."

Mr. WALTER ROCH has given notice of a new clause, which he puts forward as a substitute for Clause 43 (appointment of Local Health Committees). The proposed clause is in the following terms:—

"The Local Health Authority shall be—

(*a*) In a county borough and in a non-county borough or urban district entitled to be a pensions authority under the Old Age Pensions Act, 1908, or an authority for the purposes of Part III. of the Education Act, 1908, the Health Committee under the Public Health Acts who shall, for the purposes of this Act, add to their number by co-opting five non-members to be chosen from among members of approved societies resident within the area of their council after nominations have been invited from such societies and three women; also resident within such area and chosen by the Local Health Authority;

(*b*) In an administrative county, except as hereinbefore provided, the county council, who shall appoint a Local Health Committee for the purposes of this Act consisting of not less than twelve or more than twenty and made up as follows:—

(1) As to one-half by members of the county council;

(2) As to one-quarter by members of the local sanitary authorities, appointed by the council;

(3) As to one-quarter by members chosen by the council from among members of approved societies resident within the area of their council, after nominations have been invited from such societies;

(4) And such Health Committee shall co-opt women in addition, if necessary, to the maximum number to which it is limited as hereinbefore mentioned."

Asylum Officers (Superannuation) Bill.

Evidence is now being heard by the Select Committee of the House of Commons which has been set up to deal with the Asylum Officers (Employment, Pensions and Superannuation) Bill. The first clause of this measure lays down that male attendants and nurses in asylums shall not be employed for more than 60 hours exclusive of meal times in any week, except in case of emergencies. The secretary of the Union of Asylum Workers gave evidence strongly in support of this proposal. On the other hand, some diversity of opinion was revealed in the evidence tendered on behalf of the Asylum Workers' Association. It was stated that 110 schedules of inquiry had been sent out by this body. Replies to the number of 58 had been received, and of these 28 were in favour of the provision limiting the hours to be worked by male attendants or nurses to 60 hours a week. On the other hand, 30 pronounced against an absolute limitation of 60 hours, and some of these replies stated that members would be quite willing to work 70 hours a week if they saw a prospect of retiring after 25 years' service with a fair pension. The views of the Home Office were put before the committee in reference to the question of superannuation. Twenty-five years was looked upon by it as too short a qualifying period of service as that might lead to a man retiring on pension at 45. The Home Office suggested that the age should be at least 50.

Public Health (Ireland) Bill.

The Public Health (Ireland) Bill has received a third reading in the House of Commons. It provides that any urban district council in Ireland may, in addition to any existing powers, make by-laws providing for the inspection of all meat intended to be sold within the urban district for human consumption, and prohibiting the sale of meat within the urban district for human consumption except after inspection in accordance with the by-laws.

University of Wales (No 2) Bill.

Sir DAVID BRYNMOR JONES made an unsuccessful attempt at the time of unopposed business on Monday, July 3rd, to obtain a second reading for the University of Wales (No. 2) Bill.

HOUSE OF COMMONS.

THURSDAY, JUNE 29TH.

National Insurance Topics.

Mr. ASTOR asked the Chancellor of the Exchequer whether a woman confined in a hospital or other institution would receive maternity benefit under the provisions of the National Insurance Bill; and, if so, would any portion of it be given to the institution.—Mr. LLOYD GEORGE replied: The answer to the first part of the question is in the negative and the second does not arise. I am in communication on this matter with persons responsible for the management of homes which receive maternity cases.

Mr. ASTOR also asked the right honourable gentleman how soon after the commencement of the National Insurance Bill after it had passed into law an insured person would be entitled to sanatorium benefit.—Mr. LLOYD GEORGE answered: An insured person, if a Local Health Committee considers the case one suitable for sanatorium treatment, may be entitled to sanatorium benefit as from the commencement of the Act.

Mr. CASSEL asked the right honourable gentleman what was the average number of days of sickness or invalidity under the German insurance law in the last year for which the figures were published, and what was the average number of days allowed for in the actuarial calculations under the National Insurance Bill; and whether the average number of days of sickness and invalidity under the German law had shown any tendency to increase, and, if so, at what rate.—Mr. LLOYD GEORGE said in reply: The average number of days' sickness recorded for persons insured under the German Sickness Insurance Law in 1908 (the latest year for which complete returns have been published) was eight and a half. As compared with 1904, when sickness benefits were extended from 13 to 26 weeks, there was in 1908 an increase of about half a day per head of all persons insured. These figures cannot be used without qualification for comparative purposes inasmuch as many of the German sickness funds exercise their right to grant sickness benefits up to 52 weeks. No record is kept of the duration of sickness or disablement continuing beyond the period for which the sickness funds are liable. The number of days sickness assumed by the actuaries at each age separately for the purposes of their calculations for the National Insurance Bill is shown on p. 40 of their report. The average number per head of persons of all ages insured would require a fresh calculation.

Mr. CASSEL: Do the figures which the right honourable gentleman gave for Germany include invalidity as well as sickness or sickness only?

Mr. LLOYD GEORGE: Will the right honourable gentleman put down that question? I am not quite sure of that point.

In answer to Lord BALCARRES, Mr. LLOYD GEORGE said that on Wednesday the Government would submit a motion allocating time to the remaining stages of the National Insurance Bill.

Mr. NEWMAN asked the right honourable gentleman whether, in view of the pronouncement recently made by the Irish Bench and Bishops, in addition to the resolutions passed by the public bodies, it was the intention of the Government to withdraw the National Insurance and Unemployment Bill in the case of Ireland; and, if so, whether a general recasting of the actuarial figures on which the Bill had been based would be necessary.—Mr. LLOYD GEORGE replied: The Government have no present intention of excluding Ireland from the advantages of the National Insurance Bill.

Vaccination in Halifax.

Mr. JAMES PARKER asked the President of the Local Government Board what were the number of births, of successful vaccinations of infants, and of declarations of conscientious objection to vaccination in the borough of Halifax in the years 1905, 1906, 1907, 1908, 1909, and 1910 respectively.—Mr. BURNS furnished the following written reply: The registration subdistricts of North and South Halifax are not exactly coincident with the borough, as they contain a small area outside. The figures for these districts, so far as they are available, are as follows:—

Year.	Number of births registered.	Number of these births entered by the vaccination officer as successfully vaccinated.	Number of successful primary vaccinations at all ages.	Number of certificates of conscientious objection
1905 ...	2168	1287	No information.	
1906 ...	2165	1190	1528	235
1907 ...	2038	858	1143	275
1908 ...	2207	754	894	1067
1909 ...	1966	474	721	1002
1910 ...	1994	Not yet known.	509	1132

MONDAY, JULY 3RD.

The Sale of Milk.

Replying to Mr. BARNSTON, Sir EDWARD STRACHEY said: The Board of Agriculture has under consideration the existing provisions of law relating to the sale of milk, and inquiries are being made as to the manner in which it is at present administered by local authorities. The existing regulations are based upon the very complete inquiry made by a Departmental Committee some few years ago, and the minutes of evidence were presented to Parliament.

National Insurance Topics.

Mr. DAVID DAVIES asked the Chancellor of the Exchequer whether the sum set apart for sanatorium benefit in the Insurance Bill was to be confined exclusively to the relief of insured persons, or whether it was to be applied in such a way as to make provision for uninsured persons as well.—Mr. LLOYD GEORGE replied: The annual sum set apart for sanatorium benefit being derived mainly from the contributions of insured persons and their employers will be confined exclusively to the relief of insured persons. But the sanatoriums which receive grants of the capital sum set apart from last year's realised surplus will be able to take other patients.

Mr. DAVID DAVIES further asked the right honourable gentleman whether the scope of sanatorium benefit in the National Insurance Bill was limited to the treatment of tuberculosis in sanatoriums and similar institutions, or whether it included provision for education, tuberculosis exhibitions, early diagnosis, after care, and other means for the prevention and cure of this disease.—Mr. LLOYD GEORGE answered: It is not intended to confine the treatment of tuberculosis to sanatoriums, but the words of the Bill are intended to make it possible for the disease to be treated at clinics which could be established locally and in which the proper means to be taken for the prevention and cure of the disease could be taught. The Bill also provides that a portion of the fund available for the benefit can be applied to research.

Sir PHILIP MAGNUS asked whether demonstrators and assistant lecturers in universities and university colleges who, in consideration of the educational advantages they secured by acting as assistants to distinguished professors, were content to accept salaries of less than £160 per year, would be compelled to insure under the compulsory schemes of the National Insurance Bill; and whether the universities and colleges, as employers, would be obliged on behalf of such persons

to contribute to the insurance fund.—Mr. LLOYD GEORGE said in reply: The answer to both parts of the question is in the affirmative.

Major WHITE asked whether the Chancellor of the Exchequer had received any communications from associations of medical herbalists with regard to the National Insurance Bill, and whether he was prepared to give any facilities under the Bill to those insured persons who preferred to undergo herbalist treatment rather than that of the ordinary medical practitioner.—Mr. LLOYD GEORGE answered: I have received such communications, and they are receiving my consideration.

Mr. JAMES THOMAS asked the right honourable gentleman whether Section 13 of the National Insurance Bill, which provided for fines and suspensions of benefit for cases of misconduct, was intended to cover persons who refused to be vaccinated, even if ordered by a medical man; and, if such provisions were intended, whether he would so amend this section as to give every right to all those holding conscientious objections to vaccination.—Mr. LLOYD GEORGE replied: The rights of all conscientious objectors will, of course, be safeguarded under the Bill.

Sir W. P. BYLES asked the Prime Minister whether he had any communication to make to the House as to the Government's intentions with reference to the time to be allocated to the National Insurance Bill.—Mr. ASQUITH answered: It was proposed to have a special resolution which would give what the Government conceived to be a very liberal arrangement of time for this Bill. However, inquiry justifies us in the hope that we may secure the passage of the Bill in an equal time, or in less time, under the ordinary Standing Orders of the House. We shall be guided in our future action by the rate of progress which the Bill makes.

TUESDAY, JULY 4TH.

Vaccination Statistics.

Colonel RAWSON asked the President of the Local Government Board to state the number of births registered for the years 1903 to 1906, the number recorded as successfully vaccinated, and the number of certificates of exemption received in respect of such births; also the number of births registered for the years 1907 to 1910, the number recorded as successfully vaccinated, and the number of certificates of exemption received in respect of such births.—Mr. BURNS wrote in reply: The information which the honourable Member desires has not yet been received in respect of the year 1910, but the following statement gives the figures in respect of each of the years from 1903 to 1909, inclusive:—

Year.	Births.	Vaccinations.	Exemptions.
1903	948,271	714,637	37,675
1904	945,389	711,504	40,461
1905	929,293	705,040	44,369
1906	935,081	686,992	53,828
1907	918,042	651,060	76,709
1908	940,383	594,792	160,350
1909	914,472	547,251*	197,326*

* These figures are approximate and liable to correction.

Vaccination Officers.

Captain FABER asked the President of the Local Government Board whether vaccination officers had to send to parents a notice, Form Q, which put these parents in the way of obtaining exemptions from vaccination; whether exemptions were rapidly on the increase, seriously affecting the position of vaccination officers in a pecuniary sense; and whether he would consider the advisability of rewarding vaccination officers whether exemptions were granted or not.—Mr. BURNS furnished the following written reply: Vaccination officers are required, in the case of each child who has attained the age of three months and seven days without their having received a certificate of a kind with respect to its vaccinal condition, to send a notice known as Form Q to the parent, the object of which is to ascertain whether the parent intends to do as to the vaccination of the child, and so save the vaccination officer the trouble of visiting the home for this purpose. Exemptions have increased, and in such cases the vaccination officer does not, of course, receive payment in respect of the registration by him in his register of the successful vaccination of the child. Where a vaccination officer has suffered loss of income in consequence of the increase of exemptions I have approved proposals of boards of guardians to award him compensation.

The Teaching of Hygiene.

Mr. FERENS asked the President of the Board of Education how many of the education authorities were using the syllabus issued by the Education Department for the teaching of hygiene and temperance, and how many individual schools was the syllabus regularly used.—Mr. RUNCIMAN wrote, in reply: The syllabus of lessons on temperance for scholars attending public elementary schools issued by the Board of Education in 1909 is in use in the areas of 214 of the local education authorities of England and Wales. It is not to be inferred that in the case of the remaining 108 authorities no lessons on temperance are given. The Code commends the instruction of the older children in hygiene, particularly in relation to food and drink, including alcohol. Lessons on this subject as are not based on the new official syllabus of 1909 will be found as a rule to follow the suggestions for the teaching of hygiene and temperance which were issued in 1905. I am unable to obtain information as to the actual number of schools in which the syllabus is used. Such information could only be obtained by an inquiry addressed to each of the public elementary schools in the country, which number more than 22,000.

WEDNESDAY, JULY 5TH.

National Insurance Bill.

The House went into Committee, and after deciding not to deal with the Bill in two parts under its heading of Invalidity and Unemployment, proceeded with Clause I., which defines the persons to be insured. Two far-reaching amendments were approved of, especially securing that the class of voluntary contributors shall be limited to persons whose income does not exceed £160. The compulsory character of the insurance was maintained, and extension of benefits to married women refused, with the understanding that later the possibility of including married women, formerly contributors, will be considered, while Clause 34 is under debate.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, J. B., ET FILS, Paris.
Bibliothèque de Thérapeutique. Publiée sous la Direction de A. Gilbert et P. Carnot. Thérapeutique des Maladies Respiratoires et de la Tuberculose Pulmonaire. Par les Docteurs Ed. Hirtz Rist et Ribadeau-Dumas, Tuffier et J. Martin, Kuss. Price Fr.14.

BALE (JOHN), SONS, AND DANIELSSON, LIMITED, London.
On Writing Theses for M.B. and M.D. Degrees. By H. D. Rolleston, M.D., F.R.C.P., Senior Physician, St. George's Hospital. Price 1s. net.

APPLEYARD.—On July 3rd, at 2, Marlborough-road, Bradford, the of William Appleyard, F.R.C.S., of a daughter.

SPRAWSON.—On June 27th, at Crouch Hall-road, Crouch End wife of Francis E. Sprawson, M.R.C.S., L.R.C.P., L.D.S., daughter.

MARRIAGES.

DAVIS—RUSSELL.—On July 1st, at Balham Congregational Chur the Rev. H. H. Carlisle, Edward David Davis, M.R.C.S., L.R of 81, Harley-street, to Mildred, daughter of H. C. Russell, and Mrs. Russell, Red House, Streatham Hill.

HURTER—ROME.—On July 1st, at St. Michael's-in-the-H Liverpool, by the Rev. R. Lorimer Rome, M.A., Rector of H (uncle of the bride), assisted by the Rev. Canon Grenside, V Melling, Carnforth, and the Rev. A. F. Thornhill, M.A., V the Parish, Herbert Richard Hurter, M.D., son of the late Fer Hurter, Ph.D., M.A., and of Mrs. Hurter of Cressington P Dorothy Edith, eldest daughter of Thomas Rome of Liverpoo

MASSY-MILES—INGLE.—On July 5th, at Zion Church, Rathgar, by Rev. Canon Miles, M.A., Rector of Pangbourne, Berks (f the bridegroom), assisted by the Rev. W. J. Clarke, D.D., R the Parish, Harry Godfrey Massy-Miles, L.R.C.P. & S. Irel Marlborough-road, St. Albans, to Charlotte Elizabeth Jos eldest daughter of the late Arthur F. Ingle, Inspector of Post Offices, and of Mrs. Ingle of 24, Grosvenor-place, D Dublin.

DEATHS.

BROWN.—On June 28th, at his residence, Willesden-lane, N.W., Surgeon Thomas Edwin Burton Brown, M.D., C.I.E., aged 7

LOWDELL.—On June 26th, at Hampstead, Edward Lowdell, M in his 88th year.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL SPECIALISTS IN ANCIENT ROME.

A LATIN inscription discovered in Rome affords a further proof of the existence of medical specialists under the Roman Emperors, for in referring to a certain Secundus it bestows upon him the title of "medicus auricularius." He was a freedman of Tiberius. Another specialist with the same appellatives may be found in the Corpus of Latin Inscriptions, Volume VI., text 8908, and a passage in the Digest of the celebrated jurist Ulpian plainly indicates the medical specialist as flourishing in his era: "Medicos fortassis quis accipiet etiam eos, qui alicuius partis corporis vel certi doloris sanitatem pollicentur: ut puta si auricularius, si fistulæ vel dentium." Of course, the medici oculorii are familiar not only for their epitaphs but for their seals. It is not perhaps so well known that "medici chirurgi" are mentioned in at least three inscriptions in the Corpus of Latin texts.

CARBON DIOXIDE SNOW AS A SKIN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—Whether we be physicians or surgeons, workers in vaccines or electro-therapeutists, none of us can in these days afford to ignore the hypodermic syringe. Yet some nervous patients dread the needle almost as much as a major operation. Considering the formidable appearance of some of these instruments, and their oftentimes more than doubtful sharpness, this alarm is not altogether unreasonable. In the past pure carbolic acid and the ethyl-chloride spray have been much used as a means of dulling the pain of the needle-prick. To rely on them absolutely, and to promise a patient that no pain will be felt, is, however, to risk being subsequently told that the truth is not in you. But if the skin be first frozen for from 5 to 10 seconds with a pencil of CO_2 snow, the immediate insertion even of a large needle produces no sensation whatever. In the case of healthy skin and subjacent tissues the method is infallible, but it should be remembered that, say, in the case of an abscess, the mere *pressure* necessary to effect ingress will cause some amount of pain. By this means sera, vaccines, radium-emanation, and the like, can be injected into the most cowardly; had I no other use for my CO_2 apparatus I should consider it well worth the money as an adjunct to hypodermic medication.—I am, Sir, yours faithfully,

Bishop Auckland, June 27th, 1911. FRANCIS HERNAMAN-JOHNSON.

CRUSADE AGAINST CONDENSED MILK.

IN THE LANCET of June 24th, 1911 (p. 1737), it was stated that the Bureau of Chemistry of the United States Department of Agriculture has recommended the prosecution of certain manufacturers of condensed milk, and that the Bureau finds that much of this milk is dangerous as a food for infants. The Nestlé and Anglo-Swiss Condensed Milk Company informs us that the "condensed milk" in question is what is known in this country as "condensed machine-skimmed milk"—a product which has small right to the title of "milk."

DIET DURING MERCURIAL TREATMENT.

To the Editor of THE LANCET.

SIR,—I will thank you or some of your readers to inform me whether the old view that meat ought not to be given during an acute course of mercury still holds the field. I have chiefly in my mind mercury given for syphilis. Animal food during a prolonged chronic course of mercury is not, I take it, prohibited.

I am, Sir, yours faithfully,

June 20th, 1911. SENEX.

*** We are not aware of any such restriction, nor can we find any mention of it in the principal text-books on diet and on the treatment of syphilis. Care should, of course, be taken that the diet is plain and simple in character.—ED. L.

NEW INFANTS' WEIGHT CHART.

WE have received an infants' weight chart designed by Henry D. Kelf and published by S. Maw, Son, and Sons. This chart is for family or institutional use; it is simple and well designed. It contains spaces for the registration of the daily weights for the first fortnight and after that for weekly weighings up to the end of the first half year. This chart, numbered 4, follows the same idea as Nos. 1, 2, and 3 weight charts published by Mr. Kelf in 1902.

WARWICK X RAY PLATES.

WE have received from the Warwick Dry Plate Company of Warwick specimens of their plates for trial and report. They were first subjected to the test of keeping power, and in this respect they were in every way satisfactory. All workers in medical radiography require great speed in the plates they use, and the statement can be made in regard to the examples sent for inspection that the period of exposure was particularly short. Another very important consideration in radiography is the question of density; and here, again, the Warwick X ray plates were found to satisfy all requirements. In regard to brilliancy and detail these plates can be safely recommended to practitioners.

F. G. M. R.—1. We understand that "Spirone" has been tried in some chest hospitals and sanatoriums and that it sometimes gives relief to the cough of chronic respiratory affections. It is given as an inhalation in cases of pulmonary tuberculosis, asthma, and chronic bronchitis. It cannot, however, be regarded as a specific treatment, but may be given for the relief of symptoms. 2. In regard to the suitability of South Africa for patients with bronchitis, the high uplands of the veldt country are suitable for most pulmonary complaints, since the summer months are dry and warm and the winter is temperate, but the coast regions are not good for these patients.

"*Spes*" wants information as to the preparation (French) "dioradin"; the proprietor claims that the preparation contains terpin and iodin with radium and that it can be subcutaneously injected with good results in pulmonary tuberculosis.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
,, 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
,, 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
,, 19th–Oct. 31st (London).—Earl's Court Exhibition.
June 1st–August 31st (Squirrels Heath, Romford).—Town Planning and Modern House and Cottage Exhibition.
July 13th and 14th (Oxford).—Oxford Ophthalmological Congress.
,, 13th and 14th (Dublin).—Seventieth Annual Meeting of the Medico-Psychological Association of Great Britain and Ireland.
,, 24th–27th (Portsmouth).—British Pharmaceutical Conference.
,, 24th–28th (London).—Second International Congress of Urology.
,, 24th–29th (Belfast).—Congress of the Royal Sanitary Institute.
,, 24th–August 2nd (Belfast).—Health Exhibition in connexion with above Congress.
,, 25th–28th (Birmingham).—British Medical Association, Seventy-ninth Annual Meeting.
,, 26th (Rouen).—French National Dental Congress.
,, 26th–29th (London).—Universal Races Congress.
,, 31st–Aug. 4th (Paris).—Second French Congress of Stomatology.
,, 31st–August 5th (Dijon).—Congress of the French Association for the Advancement of Sciences.
August 1st–6th (Amiens).—Twenty-first French Congress of Alienists and Neurologists.
,, 3rd–5th (London).—British Dental Association, Annual Meeting.
,, 12th–18th (Brussels).—First International Congress on Child Study.
,, 12th–30th.—E.M.I. (Enseignement Médico-mutuel International) Tour in Scandinavia.
,, 15th–21st (Dublin).—Royal Institute of Public Health.
,, 21st–23rd (Larvik).—Fourteenth Norwegian Physicians' Congress.
,, 28th–Sept. 11th (South-East of France).—Eleventh "Voyage d'Études Médicales."
,, 30th–Sept. 2nd (Berlin).—Third International Laryngo-Rhinological Congress.
,, 30th–Sept. 6th (Portsmouth).—British Association.
,, 31st and Sept. 1st (Vancouver).—Thirteenth Annual Meeting of the British Columbia Medical Association.
Sept. 4th–9th (Yarmouth).—Sanitary Inspectors' Association. Annual Conference.
,, 5th–7th (Philadelphia).—American Electro-therapeutic Association.
,, 9th–11th (Ostend).—Fifteenth Flemish Nature and Medical Congress.
,, 11th–13th (Vienna).—German Urological Society.
,, 11th–15th (Berlin).—Third International Conference on Infantile Mortality (*Gouttes de Lait*).
,, 11th–16th (The Hague).—Thirteenth International Congress on Alcoholism.

Sept. 12th–15th.—Celebration of the 500th Anniversary of the Foundation of the University of St. Andrews.
,, 18th–23rd (Rome) Seventh International Congress of Dermatology and Syphilology.
,, 18th–23rd (Sydney).—Australasian Medical Congress.
,, 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
,, 24th–30th (Rome).—Seventh International Congress on Tuberculosis.
,, 25th–29th (Karlsruhe).—Eighty-third Meeting of German Physicists and Physicians.
,, 26th–28th (Louisville, Ky.).—American Association of Obstetricians and Gynecologists.
,, 28th–30th (Brussels).—Third Congress of the International Society of Surgery and Exhibition of Fractures.
,, 29th (Edinburgh).—Association of Veterinary Officers of Health. Annual Meeting.

September (Genoa).—International Exhibition of Marine Hygiene.
,, (Turin).—Congress of the Association of Italian Railway Physicians.
,, (London).—Bakers' and Confectioners' Exhibition.
,, (Manchester).—Second Conference of the British Hospitals Association.

September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.

Oct. 1st–4th (Liége).—Second Congress of Alimentation.
,, 2nd–5th (Turin).—International Congress of Pathology.
,, 2nd–6th (London, Royal Horticultural Hall).—Seventh London Medical Exhibition.
,, 2nd–7th (Dresden).—Third International Housing Congress.
,, 2nd–7th (Paris).—French Congress of Surgery, Twenty-fourth Annual Congress.
,, 3rd–6th (London).—Dairy Show.
,, 5th–8th (Turin).—Fourth National Congress of Hygiene.
,, 9th–12th (Turin).—Twenty-first Congress, Italian Society of Internal Medicine.
,, 9th–13th (Cologne).—Seventh International Congress of Criminal Anthropology.
,, 22nd and 23rd (Lyons).—Twelfth French Congress of Medicine.

Medical Diary for the ensuing Week.

SOCIETIES.

NEW LONDON DERMATOLOGICAL SOCIETY, Cavendish Rooms, Mortimer-street, W.

THURSDAY.—4.30 P.M., Meeting.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Cases and Card Specimens will be shown by Mr. Lawford, Mr. F. Moxon, Mr. Roll, Mr. Greeves, Mr. Cruise, and Mr. McMullen. Paper:—Mr. W. H. Jessop: Monocular Lid-wink as a Diagnosis of Long-standing Amblyopia. The Annual General Meeting will follow immediately after the Ordinary Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. J. B. R. McDonagh: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. L. Bunch: Lupus and its Treatment.
TUESDAY.—4 P.M., Dr. R. A. Young: Clinique (Medical). 5.15 P.M., Lecture:—Dr. W. Hadley: Prognosis in Heart Disease.
WEDNESDAY.—4 P.M., Mr. H. S. Pendlebury: Clinique (Surgical). 5.15 P.M., Lecture: Dr. F. W. Price: Some Newer Conceptions of Cardiac Disorders (illustrated by the polygraph).
THURSDAY.—4 P.M., Dr. W. P. S. Branson: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. C. Fox: The Erythemata.
FRIDAY.—4 P.M., Mr. C. J. Heath: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon: Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Morton: The Use of Solid Carbon Dioxide.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M.: Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Simson: Acute Conditions of the Fallopian Tubes.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Dr. Simson: Gynæcological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture VI.)
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture: Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture V.)
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: Pyuria as a Symptom of Urinary Disease.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Medical Registrar: Demonstration of Cases in Wards. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. H. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. H. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. H. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4.30 P.M., Dr. H. Pirie: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Mr. S. Boyd: The Surgical Treatment of Empyema.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. D. McKenzie: Ear.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.). Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (12th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (13th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (15th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 will be ready shortly. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—Kinematcgraph, Archiv für Experimentelle Pathologie und Pharmakologie, Journal of the Royal Sanitary Institute, Magazine of the London School of Medicine for Women, Pharmaceutical Journal, Child, South African Medical Record, Annales de Gynécologie et d'Obstétrique, Allegemeines Fremdenblatt für Sämtliche Kurorte Graubündens, Transvaal Medical Journal, Dominion Medical Monthly, Archivos Españoles de Neurologia, Psiquiatria y Fisioterapia, British Journal of Dental Science, Recueil d'Ophtalmologie, Nederlandsch Tijdschrift voor Geneeskunde, Bulletin de la Société Royale des Sciences Médicales et Naturelles de Bruxelles.

Communications, Letters, &c., have been received from—

A.—Aberdeen Education Committee, Director of; Mr. P. J. Ashfield, Rhyl; Animal Defence and Anti-Vivisection Society, Lond.; Ardath Tobacco Co., Lond.; Army and Navy Male Nurses' Co-operation, Lond.; Major P. Atal, I.M.S., Poona; Mr. J. W. Allison, Southsea; Admiralty, Medical Department of, Director-General of; Messrs. Allen and Hanburys, Lond.; Messrs. C. Ash, Sons, and Co., Lond.; Mr. R. J. Albery, Lond.; Mr. H. W. Armit, Dresden.

B.—Messrs. Blundell and Rigby, Lond.; British Diamalt Co., Lond.; Bengal Secretariat Book Depôt, Calcutta; British Medical Benevolent Fund, Lond., Hon. Secretary of; Dr. Walter Broadbent, Brighton; Bournemouth, Medical Officer of Health of; Mr. E. Bougault, Paris; Messrs. W. H. Bailey and Son, Lond.; Dr. J. Mitchell Bruce, Lond.; Mr. V. M. Brutton, Newcastle-on-Tyne; Sir William Bull, Lond.; Dr. Charles R. Box, Lond.; Mr. Clyde Brooks, Chicago; Dr. W. S. Bainbridge, New York; Surgeon J. Leslie Barford, R.N., Devonport; Birmingham City Asylum, Secretary of; Dr. E. M. Brockbank, Manchester; Mr. W. A. Brend, Lond.; *British Journal of Tuberculosis*, Lond., Editor of.

C.—Mr. P. O. Cohen, Lond.; Messrs. Constable and Co., Lond.; Dr. Leonard P. Cane, Peterborough; Sanitätsrat Dr. Eugen Cohn, Berlin; Charity Organisation Society, Lond., Secretary of; Mr. J. T. Cohen, Lond.; Messrs. Corbyn, Stacey, and Co., Lond.; Chesterfield Hospital, Secretary of; Dr. Thomas A. Chalmers, Hook; Mr. Herbert W. Chambers, Lond.; Chester, Medical Officer of Health of; Congress of the Royal Society of Public Health, Dublin, Hon. Secretaries of; Mr. Cooke, Leicester; Dr. J. B. Christopherson, Khartoum; Dr. R. A. Campbell, Dumfries; Cheltenham General Hospital, Secretary of; Coventry Corporation, Clerk to the; Coombe Hospital, Dublin, Board of Governors and Directors of; Dr. M. A. Curry, Lond.

D.—Messrs. W. Dawson and Sons, Lond.; Dr. Andrew Duncan, Lond.; Mr. K. C. Dutt, Calcutta; Dr. Lovell Drage, Hatfield; David Lewis Manchester Epileptic Colony, Secretary of; Mr. T. Dixon, Lond.; Derbyshire Royal Infirmary, Derby, Secretary of; Mr. Henry G. Dixon, Lond.

E.—Dr. F. W. Edridge-Green, Lond.; E. M. I., Paris, Director of.

F.—Mr. A. Foerster, Lond.; Fine Art Society, Lond.; Dr. R. Fortescue Fox, Lond.; Dr. J. Freeman, Lond.; Dr. F.; Miss A. F. Flood, Bexhill-on-Sea; Rt. Hon. R. Farquharson, Lond.; Dr. E. G. Fearnsides, Lond.

G.—Dr. Major Greenwood, jun., Lond.; Messrs. Henry Grant and Co., Lond.; Messrs. Gould and Portman, Lond.; G. G. F.; Dr. C. C. Guthrie, Pittsburgh; Mr. F. V. Guthrie, Pittsburgh; Gt. Eastern Railway Co., Lond., Continental Traffic Manager of; General Hospital and Dispensary, Loughborough, Secretary of; Dr. J. G. Gordon-Munn, Norwich; Mrs. N. E. Glanville, Lond.; Dr. Kenneth C. G. Gray, Glasgow.

H.—Messrs. C. J. Hewlett and Son, Lond.; Holborn Surgical Instrument Co., Lond.; Dr. Henry Head, Lond.; Mr. F. B. Hilke, Deal; Messrs. W. T. Hedges, Lond.

I.—India Rubber, Gutta Percha, and Telegraph Works Co., Lond.; *Indian Medical Record*, Calcutta, Manager of.

J.—Dr. Robert Jones, Woodford Bridge; Mr. H. W. Jackson, Lond.; J. M. L. B.; Dr. H. C. Jamieson, Red Deer, Canada.

K.—Messrs. R. A. Knight and Co., Lond.; Dr. Knight, Edinburgh; Mr. Theodore Kitching, Lond.; Captain H. C. Keates, Jullundur, India; *The Kinematograph and Lantern Weekly*, Lond., Editor of; Mr. S. W. Kelkar, Aurangabad; Mr. W. B. Kebble, Lond.; Mr. Vishnu T. Korke, Liverpool.

L.—Leeds Hospital for Women and Children, Secretary of; Leeds Public Dispensary, Secretary of; London Hospital Medical College, House Committee and College Board of; Local Government Board, Edinburgh, Secretary of; Mr. H. The Lumleian Lectures

ON

A CLINICAL STUDY OF CARDIO-VASCULAR DEGENERATION.

Delivered before the Royal College of Physicians of London

BY J. MITCHELL BRUCE, M.A., LL.D. HON. ABERD., M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON THE PRACTICE OF MEDICINE AT, AND CONSULTING PHYSICIAN TO, CHARING CROSS HOSPITAL, ETC.

LECTURE II.[1]

Delivered on March 28th.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—In my first lecture I dwelt upon the importance of tracing cardio-vascular degeneration in every instance to one or other of its recognised causes, and I gave figures of the relative frequency of these in 100 cases of my own, casually taken. I then proceeded to examine the clinical characters peculiar to the disease as it is produced by several causes, beginning with syphilis.

A METABOLIC GROUP.

Passing from the consideration of the syphilitic group, let me give you an outline of a case which will introduce us to the next group that I have arranged to submit to your consideration.

A patient was sent to me complaining of attacks of a sense of fulness of the head and inability to conduct his business, partly at least a result of a severe course of treatment at Harrogate based on a diagnosis of free living. His heart was large, his radial thickened, his blood-pressure low. He gave me a history of syphilis, and this appeared to be reasonably regarded as the cause of the cardio-vascular changes and the cerebral disturbance. But closer examination revealed other features of the case which enabled me to correct my first impression. There was no physical evidence of valvular disease or of aortic atheroma, and the urine proved to contain a small percentage of sugar with a very moderate specific gravity. Suspicion was now diverted from syphilis to metabolic disorder as the cause of the disease, consequent on free indulgence in food and alcohol, and the whole history of the case from the first, including the employment and effect of spa treatment (and, let me add, the course of the case up to the present—fully two years), proves the correctness of the etiological diagnosis.

I have chosen this case, first, to illustrate the possibility and importance of disentangling the possible causes of cardio-vascular degeneration when they come together in a patient's history, and, secondly, to introduce us, as I have said, to another group which I propose to call for purposes of description the metabolic group.

Disorders of nutrition are universally regarded as causes of cardio-vascular degeneration, and the literature on this part of our subject is very extensive. A strict critic might ask with reason in what these disorders, to which we attach so much etiological importance, consist. Can we demonstrate that the blood is deficient in any of its constituents, or that it contains an excess of any of its constituents, or that an abnormal body can be isolated from it and identified and proved to damage the arterial walls and the cardiac valves?

Since I could not answer these questions to satisfy myself, I adopted another evidence of metabolic disorder—the presence of sugar in the urine. This is a test easily employed, and the result cannot be gainsaid.

Clinical Study of Metabolic Group.

I have selected for study at this time the cases of 20 individuals between the ages of 44 and 70 in whom cardio-vascular degeneration proved to be associated with glycosuria. I say glycosuria, not diabetes, for although two patients out of the 20 did die with diabetic coma, the disease belonged in them for a time, and in all the other members of the group from first to last, to the mild senile type, as their ages prove, sugar being small in amount and frequently intermittent in its appearance. Further, along with sugar there was found in 75 per cent. of the cases albumin, also moderate or scanty in amount, and also intermittent.

This is a type of metabolic disorder familiar to all of us, yet, as far as my search has gone, little noticed in the literature of albuminuria and diabetes, with the exception of a paper by Dr. Bence Jones in the thirty-sixth volume of the Transactions of the Royal Medical and Chirurgical Society. In its prognostic significance it is paradoxical, for, although it is an association of two conditions each regarded with concern, it usually is less serious than either of them often proves singly.

The result of a study of this group of cases proved to be interesting, and I venture to say important. In particular, the physical signs are strikingly different from those which we found to characterise syphilis of the cardio-vascular system, as will be apparent presently. Of the 20 individuals, 18 were men of the average age of 57⅔ years, and 2 were women of the average age of 54½. The majority of the men were occupied with professional work or business, involving in some instances not only intellectual stress but worry in different forms and degrees. As for their habits, one-fifth of them were teetotalers, one-half of them used alcohol in moderation, only one was thoroughly intemperate, and the rest of them had "lived freely," as the saying goes. On the other hand, a considerable proportion were known to have eaten to excess. More than one-half of them had led sedentary lives, and had enjoyed but little relaxation during the years of mental work. In more than half the instances they were stout or actually obese; and the disorders and disabilities connected with corpulence naturally complicated their complaints—want of vigour; gastric, hepatic and intestinal disturbances; gall-stones; bilious headaches; and, in a later stage, disease of the retina and paralysis. Gout had occurred from time to time in nearly one-half, mostly taking the irregular forms of eczema, lumbago, sciatica and nodi digitorum.

It was not difficult to appreciate the character and disposition of these subjects of intermittent glycosuria. Possessed of a hearty appetite themselves, they are of distinctly sociable habits. If they have retired from successful work they are sedentary, easy-going and self-indulgent. If they are still engaged in business we find them difficult to control for any length of time, guilty of lapses from our prescribed regimen as often as temptation presents itself in their commercial relations, and ready to express a hearty contempt for small allowances of food and drink. Arterial sclerosis of this type is one of the chronic diseases which, as Sydenham says, "proceed from ourselves." A fact of great importance in its bearing on causation in these individuals is that in at least one-quarter of the cases a family history of heart disease was obtained, and of similar or allied metabolic disorders in many of them.

The subjects of degeneration of the heart and arteries associated with glycosuria suffer from all the ordinary symptoms of cardiac disability and distress, variously distributed in the different instances. These I found put prominently forward in 65 per cent. of the cases; in the remaining 35 per cent. the first symptoms did not relate to the circulation directly. Very curiously, the chief complaint was of dyspnœa, whether on exertion or paroxysmal. Next in frequency to this came pain in the chest; and it is worth recording that whereas in syphilis of this region pain is in half the cases anginal—that is, referable to the aortic area, it is in glycosuric cases quite three times as often strictly præcordial—that is, regionally related to the heart.

Physical Signs.

But it is when we come to the physical signs that the differences between the clinical characters of these two great groups of cases of cardio-vascular degeneration point unmistakably to the areas affected by syphilis and metabolic disorders respectively—differences so marked as to be diagnostic. In glycosuric cases the aortic diastolic murmur which figures so largely in syphilis (50 per cent.) was never found. On the other hand, an apical systolic murmur, which it will be remembered is relatively uncommon (only 10 per cent.) in syphilis, was present in no fewer than 55 per cent. of metabolic cases. These figures may not appeal to us as first, but let me suggest that in them we find not only one useful means of making a differential diagnosis of the nature of degeneration of the cardiac valves, but also an evidence that whilst syphilis is a selective process in the

[1] Lecture I. was published in THE LANCET of July 8th, p. 69.

distribution of its lesions, and affects the arch of the aorta in particular, degeneration in association with glycosuria is not so. Not that it spares the aorta, if we can rely on clinical evidence, for in more than one-half of my cases I found a direct basic murmur, and in 35 per cent. of them manubrial percussion-dulness. But, if my observations are to be trusted, the morbid process does not descend on the aortic cusps as we saw that it descends in syphilis; or, if it do so descend, it is not so severe or so damaging as to render them incompetent, and this although it can be observed invading the mitral valve along with the aortic arch.

The heart was found to be enlarged in more than 80 per cent. of the cases. In more than half of these instances the impulse was weak or altogether imperceptible; and, where there was no murmur present, both sounds often were found feeble, a loud ringing second sound in the aortic space being infrequent. With a large and relatively feeble heart it is more than possible that the apical systolic murmur so often met with may have been dynamic; and in support of this interpretation of it are the facts that I have repeatedly found it variable—that is, that it may be intermittent, and that in one patient it once was lost immediately after walking exercise and again after a little whisky. In the last stage of the disease—cardiac failure—these signs naturally are modified.

The characters of the radial artery and pulse on the whole correspond with these observations on the heart. I found the vessel sclerosed in 80 per cent., but a tension above the ordinary in only 10 per cent.; indeed, in 65 per cent. the pulse was definitely soft. Thus the pathological process in this type of cardio-vascular degeneration again appears to be general, not local or selective, in distribution, and to be characterised by deficient vascular tone as well as by cardiac feebleness. The pulse is often found irregular, and I have been struck by the relative frequency of tachycardia in these glycosuric subjects.

Clinical Course.

The clinical course of cardio-vascular degeneration associated with glycosuria is usually slow. In a few instances the patient comes to us so early with a complaint of debility, that along with this and glycosuria and some or all the characteristic features that I have sketched, we may find an irregular pulse and præcordial oppression or actual pain, but no physical signs of actual lesion, no radial sclerosis, no aortic murmur, no mitral murmur. But far more commonly by the time that we are consulted the evidences of degeneration are already unmistakeable. Of my complete series of 38 cases which I analysed from this point of view, I found that the first symptoms were on an average referred to the fifty-second year of life. The non-fatal cases when I last heard of them had lived 8½ years. Of those whom I succeeded in tracing, 31·5 per cent., after suffering for 12½ years, had died at an average age of 62 years. These average figures, so different from those which we found under syphilis, are of real diagnostic value and of general prognostic value also. But they are of little value in individual prognosis. A friend of my own, who died at 65, had had intermittent glycosuria for 32 years under the care of Dr. Pavy, Dr. William Ord, and myself in succession. For the last seven years, at least, of his life his radial arteries were the thickest I had ever felt, and at last he was found dead in bed, after having complained for only two days of acute and persistent pain across the upper sternum and between the scapulæ. Death in this sudden fashion is not an exceptional termination of these cases. It occurred in 25 per cent. of those traced to a fatal determination. 18 per cent. of the same patients died with coma, 9 per cent. with paralysis, some with angina pectoris, and a few from ordinary cardiac failure with dropsy. I have observed at least one case drifting slowly into chronic nephritis.

In connexion with the clinical course of associated glycosuria and arterial sclerosis there can be no question but that cases are met with in which cardio-vascular symptoms have preceded the discovery of sugar by many years. It might be contended that this observation proves that the association is accidental only, not organic. It may be so in a few instances. But we must not forget that (as Bence Jones said many years ago) glycosuria in old age may pass entirely unnoticed, partly because it is intermittent, partly (as I have already ventured to remark) because the busy practitioner may be tempted to be satisfied with the discovery of cardiac disease and a thickened pulse, and not trouble to search for sugar. Further, I am quite willing to accept the opinion of some authorities, based on post-mortem evidence, that glycosuria is occasionally an effect, not the cause, of cardio-vascular disease—an effect of sclerosis of the pancreatic arteries.

It is unnecessary for me to ask under which of the two great classes of influences, nutritional or dynamic, that affect the walls of the heart and arteries unfavourably this group of cases falls. In their very essence they involve malnutrition, and we have found that only in exceptional instances is the blood pressure other than low. Professor Osler, in discussing the causes of arterial sclerosis, mentions "the action of poisons retained within the system." It is worth consideration that tissues which are poisoned by products of mal-assimilation are starved at the same time. The autogenous poisons are products of food materials that have missed conversion into proper elements of nutrition. This, indeed, is proved by the hearty appetite that besets these subjects and leads them, as we have seen, into unfortunate habits of living. Our best authorities maintain that large eating, or, as our distinguished Fellow, Professor Bäumler, phrases it, "Misverhältniss zwischen Zufahr und Verbrauch," raises blood-pressure; and I agree with them. But my experience is that when it does so, gout, not glycosuria without gout as in my present group of cases, is the ready guide to the intimate character of the disorder. Glycosuria, I need not say, produces a profound effect on the nutrition of the tissues. Its occasional association with peripheral neuritis along with arterial sclerosis is a proof of this. A few years ago I was asked to see a gentleman of 65 years, but looking older and worn, who had fallen asleep with his feet on the fender of the hall fire the previous evening, and woke up to find them severely burnt. His medical adviser promptly diagnosed anæsthesia from peripheral neuritis, suspected glycosuria, and found sugar. The tibials proved to be sclerosed, and the patient died in a few days. As neuritis is the result of the supply of impure and impoverished blood to the nerves, so I suggest aortitis is produced in these glycosuric patients. Strain of the walls may follow, but it is an effect of an internal pressure that is not absolutely high, but high in relation to the diminished resistance of diseased walls.

A GOUTY GROUP.

Acute gout is universally acknowledged to be related etiologically to cardio-vascular degeneration. According to my inquiry in the 100 cases already mentioned it was found in no fewer than 44·5 per cent. These include instances in which it was associated with other so-called causes; and, indeed, one of the difficulties of the investigation of the etiology of arterial sclerosis and cardiac degeneration is to eliminate the possibility of gout. Similarly, it is not an easy matter in studying the influence of gout in this connexion to eliminate glycosuria; and I would say at once that the figures which I shall presently give you relate to cases in which no sugar was ever found.

The evidence of true or regular gout that I accepted was the presence or a sufficient history of at least one acute attack of characteristic podagra or acute arthritis elsewhere. Familiar although this type is, let me introduce a short description of it with a typical case:—

A lady who has passed middle age complains of tinnitus only: not of anything directly connected with her heart. Her mother, she says, had a similar trouble and gouty hands; her younger sister, who accompanies her, has nodi digitorum. The patient herself has had acute gout once in her great toe, and her fingers are characteristic. She is temperate in the use of alcohol; but according to her sister, "she eats everything and anything and at any time." She has had no acute disease and has no worry. Now this woman has a maximum blood-pressure of 200 mm., and a mean of 120 mm.; and the radial wall is distinctly thickened. I find a systolic murmur in the aortic area, which is conducted into the carotid, an area of impaired resonance over the manubrium and a systolic murmur at the apex; and there is a good impulse somewhat far to the left. The urine contains neither sugar nor albumin nor casts. Her single complaint is of tinnitus, with deafness of one ear; but she allows that her breath is short on exertion. You will agree with me that this case conforms to a type which we see almost daily.

Like, and yet in some ways unlike, this case of true gout and cardio-vascular degeneration, let me describe that of

another patient which illustrates the relation of irregular gout to disease of the heart and vessels.

A single lady of 51, living in an extremely quiet way, consulted me for what she called "general weakness." This, it was suggested, was a result of devoted attention to her aged and invalid mother. I found that her father had died suddenly; that she had suffered from migraine until she gave up meat, and also from eczema; and that 18 months previously there had occurred a single attack of vertigo and sickness, followed by impairment of hearing and tinnitus. From that date the patient said she "had never been the same woman," and had felt the heart beating in her chest. Nine months later she was taken with pain in the knee on resuming a meat diet. Examination revealed a surprising degree of cardio-vascular degeneration: the heart greatly enlarged, with a heaving impulse; the first sound reduplicated universally; the second accentuated universally, ringing in character over the aortic area, and followed by a diastolic aortic murmur; the radial artery thick and visible, full to the finger, yet half-collapsing in character; the urine over-abundant, of low specific gravity, and very slightly albuminous.

Clinical Characteristics.

As in these two cases, the patient's first complaint to us may be of something connected only indirectly with the heart or vessels, or of the joints. But quite as often it is of pain in the chest, and, let me note, more often, as in syphilis, of anginal than of strictly præcordial pain as in the glycosuric group. Closer inquiry elicits a confession of dyspnœa and palpitation on effort, and of occasional faintness and consciousness of intermittency of the heart. In more than a quarter of all my cases I found albumin and in a few glycosuria; but, as I have already said, these cases I excluded from the present series for the purpose of analysis.

In at least 90 per cent. of cases of cardio-vascular disease associated with gout the heart is found to be enlarged; in one-half of them with a normal or increased impulse—in contrast, let me remind you, with glycosuric cases. Again, as in them, the prominent physical signs are an aortic systolic murmur and an apical systolic murmur, the aortic rather more frequent than the other. Along with these we find what we miss entirely in glycosuric cases, an aortic diastolic bruit, rare indeed, but definitely to be reckoned a possible feature of a gouty heart, reminding us of the angina and the more vigorous impulse, and accompanied in a good many instances with dulness over the manubrium, the whole significant of tension within the arch. Corresponding with this I found the pulse-tension above the normal in about half the cases, and the radial more or less sclerosed in all but a small percentage. In about 15 per cent. the pulse was irregular or intermittent.

With the symptoms and signs proper of this type there are very commonly associated characteristic manifestations of chronic gout. The face presents an uniformly sleek, anæmic appearance, and is often expressive of depression with irritability. Arcus senilis may be noted in the cornea. The fingers are nodous or more markedly deformed. The muscles are soft; the tissues as a whole flabby. The chest is commonly emphysematous in some degree, with the familiar rhonchi of slight catarrh. Digestion is variously disturbed; the liver and bowels are inactive; the urine consequently is abnormal in different respects. The patient's sleep is interrupted in the middle of the night, not by an attack of acute gout, for which he may be longing, but by a fit of unutterable depression, with miserable memories and forebodings of evil. But I need not enlarge this reproduction of a clinical picture familiar to you all. My point is that these characters are of essential value in the diagnosis of the type.

Clinical Course.

No particular age can be named as the time at which the symptoms of cardio-vascular degeneration begin to be felt by gouty subjects. I have records of cardiac distress at 32, but that was in a man who had inherited gout powerfully, and had had to give up athletics after running twice in the 'Varsity sports. On the other hand, gouty men of 70 have told me that they had only just begun to feel their hearts. The average date of the first symptoms in all my cases is the fifty-fifth year. The duration is equally variable—the average in survivors 9½ years, with a maximum of 30 years; in fatal cases, 7 years, with a maximum of 15 years. 35 per cent. of the cases I have seen in the course of the last 13 years have died, but not before the average age of 65, one indeed in his eightieth year and one in his eighty-first, and only one of them before 55. These are dry figures to recount, but obviously they are interesting and also comforting in their prognostic aspect, and not without some value in connexion with life assurance.

The manner of death was various; most commonly with cardiac failure, but frequently with cerebral hæmorrhage or from Bright's disease. Death was sudden in one instance. And some of the patients perished of intercurrent or entirely independent diseases.

It is often possible to trace with clinical exactness the progress of the lesions throughout the cardio-vascular system in these cases of gouty origin. With little or no evidence at first of other than the disorders characteristic of goutiness, there are discovered as year follows on year a direct aortic murmur and enlarged heart, an apical systolic murmur, dulness creeping over the manubrium and down the sternum, possibly a diastolic murmur, a rising blood-pressure, the appearance of albumin, decline of strength and substance, œdema, pulmonary congestion, and the usual train of symptoms and signs characteristic of failure of the heart. In other instances the course of the disease is suddenly interrupted by a fit of apoplexy, which ends in death. Or, short of death, the result may be temporary paralysis, which is repeated again and again, of various degree and distribution, alternately or otherwise associated with attacks of angina or of paroxysmal dyspnœa.

Under which of the two great orders of pathogenetic influences acting on the heart and vessels does gout fall? Under both. In our analysis of the symptoms and signs in it, as distinguished from those which we found associated with syphilis and glycosuria, we have been introduced to evidences of high pressure—in the force of the heart, in the auscultatory phenomena, in the dilated aorta and angina, in the tense as well as thickened pulse, and in deaths from chronic Bright's disease or from cerebral hæmorrhage.

PHYSICAL STRAIN.

1. *After-history of Juvenile Strain.*

A small proportion of cases of cardiac enlargement, with or without arterial sclerosis, may be traced to physical strain in early manhood. At any rate it is not uncommon to find in the man of 45 or 50 or more, who comes to us with complaints of his heart, of shortness of breath, ready exhaustion, and possibly depression and the ordinary signs of a large heart without murmur, a history of vigorous athleticism at school or college, it may be of acute cardiac strain, and to get from him a spontaneous statement that he "did too much then," and has "felt the heart at times ever since."

A tutor of 37 complained of feeling his heart in the school gymnasium. Twelve years previously—that is, at 25—when training in gymnastics during a severe catarrh, he was suddenly taken with great palpitation and a sharp shooting pain at the left margin of the epigastrium. The doctor considered that the heart was strained, and ordered complete rest for a fortnight, with the best result. Seven years later he had again to give up physical exercises because of his heart; "the least thing," as he said, "caused palpitation." For a month before I saw him he had suffered from præcordial discomfort and palpitation on even slight exertion. This man had had no acute disease of any kind, and had led a temperate life. I found the ordinary signs of enlargement of both sides of the heart, with epigastric pulsation; no murmur; a greatly accelerated, regular, soft pulse, free from thickening of its walls. It will be observed that the patient was only 37. I heard of this patient four months ago, after an interval of ten years. Under the careful control of his doctor in respect of exercise he keeps well and continues his professional work.

When a series of cases of this order are analysed, with particular care to exclude syphilis, gout, rheumatism, and alcohol as possible causes of the original cardio-vascular damage, a reasonably trustworthy conclusion can be reached with respect to their characteristic features. The patient complains that he "feels his heart," that its action is irregular—often amounting to palpitation on moderate exertion, or even in ordinary exercise; and that therewith he has a distressing sense of oppression or tightness in the præcordia, which may pass into or be mixed with pain, sometimes anginal. Faintness is a relatively common symptom in these subjects, whether it be true faintness, or

vertigo, or a sense of exhaustion. Dyspnœa is not put prominently forward as a complaint, the truth being that active exertion causes distress and commonly is avoided.

The physical signs corresponding with these symptoms are such as we should expect to find in persons who had dilated their hearts by physical exertion many years before. Valvular murmurs are so rare that they may be referred to some intercurrent cause, or to some undetermined influence in the previous personal history of the patient. Invariably there is evidence of cardiac enlargement—with a few exceptions enlargement of both sides, and a weak or moderate impulse; often there is an irregular rhythm. In more than one half of my cases I found the radials sclerosed; in two-thirds the pressure was low or normal, in one-third high.

I should best describe the disability of this order of cardio-vascular disease by saying that it is due to, or consists in a measure of loss of that reserve of extensibility and associated elasticity on which the successful action of the cardiac chambers depends in the presence of physical stress beyond the mean. These patients are comfortable when at rest or when walking quietly on a level road, but they suffer as I have described when they attempt to negotiate acclivities of different gradient in different instances, and no doubt they suffer more readily with advancing years.

Of course, it cannot be maintained that the condition of the circulation as we find it in this class of cases at the age of 50 or upwards is entirely referable to physical strain in youth. The dilated heart and thickened arteries have passed through a period of 30 years' exposure to the influences that are familiar to us as embarrassing and threatening compensation in valvular disease. Work in different forms, physical or mental, worry, consciousness that the heart is damaged and fear to know the whole truth, over-indulgence in food, alcohol and tobacco, gout, intercurrent disease—one or more of these may be assumed to have been at work and imperilling compensation. In particular, the patient's disposition to abuse physical exercise, which has been but partially restrained by the handicap of a dilated heart, may have led him into fresh trouble.

An old pupil of mine at Charing Cross Hospital was told 20 years ago by my colleague, Dr. F. W. Mott, that he had strained his heart racing, and was duly cautioned. Ever after, he says, he felt his heart somewhat, but he was able to carry on a country practice. Then at the end of last year, cycling up-hill one day, he was suddenly taken with pain a little to the left of mid-sternum. The amount of exercise he can take comfortably is now definitely limited, because of palpitation and a suffocating feeling which overtakes him, followed by dyspnœa and even pain. After a heavy day's professional work he will wake in distress and have to sit up in bed with palpitation. This man has no cardiac murmur, but the ordinary signs of a large, feeble heart, with the second aortic sound relatively accentuated and clear; his pulse is neither tense nor sclerosed.

In the majority of instances the fresh stress has been less severe but more continued—indeed, continuous. It has been the stress of professional life, of a hard-worked parson or medical practitioner; or it has been of another form—the week-end stress at golf or hunting, or otherwise, of the old athlete condemned to an office, who seizes the opportunity to take exercise of so active a character that the heart, now fallen out of condition, is embarrassed by an internal pressure which previously produced only wholesome reaction and a sense of enjoyment. In the disease itself under favourable circumstances there is nothing essentially progressive. But as in the years that have passed before these subjects come for advice, so throughout the subsequent course of their cases under our observation, they are liable to become victims of failure of the heart from any of its ordinary causes. The average age of my patients belonging to this series when first seen was 54 years; and the average duration of the cardiac disablement since the acute strain, when I last heard of them, whether dead or still living, was 34 years. The patients that have died reached the average age of 66.

There can be no question in respect of this class of cases which of our two orders of influences—physical stress or disordered nutrition—has affected the structure of the cardiac and arterial walls. There is a limit to the physical stress that these tissues can bear without undergoing histological change. This change is in part resistant and conservative in its significance at first, but ultimately pathological and disabling. Some authorities maintain, not without reason, that whatever may be the effect of intermittent rise of arterial pressure artificially produced in animals, it is impossible for a healthy man to exert himself physically so severely as to damage acutely a heart and vascular system that are perfectly sound. But that is just the point. Not every man who regards himself as well and sound is so; and in this way strain of apparently healthy hearts and arteries (which, after all, is an exceptional occurrence) can be accounted for. The inherited quality of the material of his tissues, or their condition of "form" at the moment of stress—possibly itself the effect of over-training, for young athletes often live unwisely—may be insufficient to resist the rise of blood-pressure which has been abundantly proved to attend muscular exertion. In less sudden and severe, but repeated or continuous, forms of exercise the changes in the walls of the heart are purely conservative—hypertrophy of the muscular elements, strain-hypertrophy of the fibrous. I have repeatedly met with thickened radials (sometimes with a thickened right radial only) in young engineers or others engaged in severe manual labour. But we have seen that thickening of the intima may in turn provoke further rise of tension by narrowing the vascular lumen, and a vicious circle involving heart and vessels may become established. Further, a condition of compensation, immediately salutary and conservative of life though it be, is essentially more precarious, more difficult of maintenance, than is the condition of ordinary physiological activity. The circumstances of life in most men between 20 and 50 are sufficiently trying to interfere with it; and at the latter age, or shortly after, they come to us with the symptoms and signs which I have attempted to sketch.

2. *Strain of the Senile Heart.*

I will next introduce you to a group of cases in which the relation of physical stress to the nutritional condition of the cardio-vascular walls is the reverse: where the original stress falls upon a middle-aged or old heart already unsound.

A medical friend of my own, aged 53, consulted me in December, 1908, for pain in the chest and down the left arm, from which he had suffered ever since bicycling from London to Brighton and back in one day shortly before. From that time he had not been free from distress as often as he walked up a hill or took his bath. I learned that he had worked hard, and had much worry; was perfectly moderate in the use of alcohol and tobacco; and had not had rheumatism, gout, or syphilis, but both pneumonia and influenza. This man, within a few weeks of the event that had caused him serious concern, proved to have an enlarged heart, with somewhat weak cardiac sounds—the first suspiciously impure in the mitral area—and thickened radials, the left radial being visible and tortuous with a maximum blood-pressure of 140. The pain for which he came to me was centred in the third left interspace, about an inch from the sternal border, and travelled thence along the second rib to the left scapula and down to the elbow. He suffered neither from faintness nor from palpitation, nor indeed from actual dyspnœa on moderate exercise on the level. The urine was free from sugar and albumin. It was clear to me that this patient had strained his heart at 53 by an extremely unwise—because severe and prolonged—muscular effort, but that his heart and vessels had been unsound before the event.

Of cardio-vascular disease of this character I have examined carefully the cases of 20 patients, 17 men and 3 women, of the average age of 58. I find that a variety of causes had interfered with the nutrition of the cardio-vascular walls in the different instances before the strain, and reduced their resistance to internal pressure, including gout and goutiness, the cares and worries of business, influenza, tobacco, and sedentary life with over-eating. In one instance the only circumstance predisposing to physical strain after 50 that could be ascertained was family inheritance of cardiac degeneration. A married lady aged 56 was sent to me in 1898 suffering from palpitation and occasional attacks of alarming cardiac failure. I found that she had led an active, energetic life, and had enjoyed perfect health, with the exception of an occasional attack of influenza, from which she made perfect recoveries. Three months before I saw her she was working hard on her bicycle up a short, sharp incline, when she was taken with pain in her left side, so severe that she had to dismount. Nothing more occurred at the time, but next morning her

medical attendant was urgently sent for. On rising in the morning she had been again seized with pain in the left side of the chest, so violent that she became partly unconscious, and was found pale and exhausted, with a pulse of 50, very weak and compressible and intermittent every tenth beat. After a few days' rest she had improved, but rising—against instructions—on the seventh day she had had a second attack in her bath, from which she very slowly recovered, being unable to rise without return of faintness, the pulse continuing of the same character. When I saw her I found the heart enlarged, with a definite impulse but irregular rhythm, an imperfectly developed systolic murmur replacing the first sound at intervals, a radial pulse scarcely perceptible, quite irregular, and not thickened.

Now this patient, with a personal history so relatively favourable, had lost her mother from fatty degeneration of the heart at 68, a maternal uncle and aunt both from heart disease about the same age, and a brother from heart disease at 30, and a sister was suffering from some form of cardiac affection at the time of her illness. She herself died eight years later. And I may remind you that amongst the hearts that are strained after 50 are hearts which have been already strained in some degree in youth and partially disabled. A country parson who had had to give up athletics at Oxford after running two hard races in close succession confessed to me that at 50 he fell off his bicycle in a faint.

Thus our two groups of cardiac strains, juvenile and senile, may be associated. Naturally there might be admitted into this group, if it were enlarged indefinitely, cases of physical strain in middle or advanced life of hearts that had been previously damaged in any respect or by any means whatsoever—by rheumatism, for instance, or by syphilis, as in several instances which I have already described to you.

In one sense cardiac failure may be said always to be the result of cardiac or cardio-vascular strain, relative if not absolute. The pressure within the chambers of the heart, the load that has to be moved, has been relatively too great for the driving power of the walls. But my present series consists only of cases in which acute strain came as a surprise, there being no knowledge (or at least no practical recognition) of previous damage of the heart, although in some instances it was believed to be "weak," or was occasionally disturbed. And further, in these cases the symptoms of strain, once developed, continued to recur indefinitely on muscular exertion.

The particular form of physical stress that falls upon the insufficiently resistant heart of a man in middle or later life is very various. The exertion of mountain-climbing, of keeping pace with younger men shooting in line, of bicycling with boys who set the pace, of hurrying to catch a train or the post (or to fetch an instrument, which I have known to strain a doctor's heart)—these and others are familiar incidents. One of the gravest cases of strain in middle age that I have ever met with was that of a distinguished sculptor, who ruptured his aortic valves in saving a heavy bit of precious statuary from falling. I have already referred to the effect on the gouty heart of unwise exertion at the week-ends.

In strain of the senile heart the symptoms subsequent to the acute pain or faintness of the actual event itself, when regarded comprehensively, resemble in one respect those which we have just studied in the after-history of juvenile strain. As far as they are characteristic, they are manifestations of the loss in different degrees of that reserve which the elastic and muscular walls of the heart possess for meeting extraordinary calls upon their properties and functions. In these subjects physical exertion of even moderate degree, different in different instances, is attended with a sense of discomfort, oppression or pain in the chest, and it may be down the arms, with consciousness of palpitating, irregular action of the heart. Each patient comes to learn the amount of the handicap of his heart and to moderate his work or exercise accordingly. Efforts after meals are particularly likely to provoke attacks. Rest affords relief. Naturally, in the relatively few instances in which the valves have been damaged or the orifices permanently dilated, the symptoms are more severe, and of the characters and associations familiar in the different forms of chronic valvular disease.

The physical signs of strain of the senile heart always include those of cardiac enlargement, and the impulse almost invariably is weak. Most commonly I have found the cardiac sounds small or feeble, but the second often has a finely ringing quality. In 25 per cent. of my cases there was an apical systolic murmur; in 15 per cent. an aortic systolic murmur; in two cases a diastolic aortic murmur. The radial was sclerosed in rather less than half the cases, the tension low in more than three-fourths.

I have incidentally referred to the *clinical course* of strain of the senile heart. The limitations of its capacity for other than moderate physical effort naturally increase with age, and with the accumulation of other causes that tax the nutrition and strength of the heart. In my series the average age at which symptoms made their appearance was 56; the average duration of life thereafter in patients still living has been seven years, and in some considerably more. In fatal cases it was six years; but one patient died two months after climbing the steps of Milan Cathedral; another with ruptured aortic valves survived only eight months; a third, with a similar lesion, two and a half years. Of 20 patients belonging to this series seen during the past 13 years one-half are known to have died, some of them from cardiac failure, some suddenly with angina. Of the living those of no occupation have sent me a relatively favourable report of themselves; others who have been tempted to continue in business or to indulge in sport have returned with fresh complaints of distress.

In physical strain of the senile heart and vessels both of the two great orders of influences that may damage the cardio-vascular system are again found at work. But here, as I said, the order of invasion is reversed. The cardiac and vascular walls are first poisoned or impoverished and then over-stretched. We have seen that many of these subjects had already presented definite evidences of impairment of cardiac or arterial nutrition before the event which damaged them permanently. But Professor Dixon has demonstrated to us experimentally that violent dumb-bell exercise in men (presumably sound men) of 60 raises the blood-pressure to twice the height that it does in men of 23, or even higher. This observation of his proves not only how foolish it is for men over 60 to attempt, as some do, to keep pace with their juniors in severe physical exercise, but that their handicap, as I have called it, is heavier than most of them would condescend to acknowledge.

THE TREATMENT OF PHTHISIS AND HÆMOPTYSIS BY ARTIFICIAL PNEUMOTHORAX.[1]

BY CLAUDE LILLINGSTON, M.B., B.C. CANTAB.

LITTLE notice has hitherto been taken in England of the treatment of phthisis by artificial pneumothorax which was advocated by Forlanini as early as 1882, and which has, undoubtedly, already saved the lives of many in the last stages of phthisis. In my own case the treatment was adopted only when sanatorium and other forms of treatment had failed to arrest the disease, and the prognosis was as unfavourable as could be. The success which ensued I have since seen repeated again and again in other patients. Samson in 1910 estimated that the number of published cases exceeded 400. Writers, such as Saugman and others, have only published those cases in which the treatment has lasted a considerable time. It is therefore probable that the number of patients who have undergone this treatment already far exceeds the above figure.

The quantity of foreign literature on the subject is already great. It is all the more striking to find so few original articles on the subject in the English medical press. The lack of interest in the treatment has had this ludicrous effect, that English pneumothorax patients at Davos were unable in the summer of 1910 to return to England owing to their inability to find anyone in this country with sufficient knowledge of the treatment to continue the injections of nitrogen.

It is, perhaps, one of the most striking features of the treatment by induction of an artificial pneumothorax that it has hitherto been almost exclusively applied in advanced cases of phthisis, and that in spite of this selection of the unfittest such good results have been obtained. In this respect the treatment compares favourably with other remedies, the efficacy of which seldom

[1] Extract from Thesis for degree of M.D.

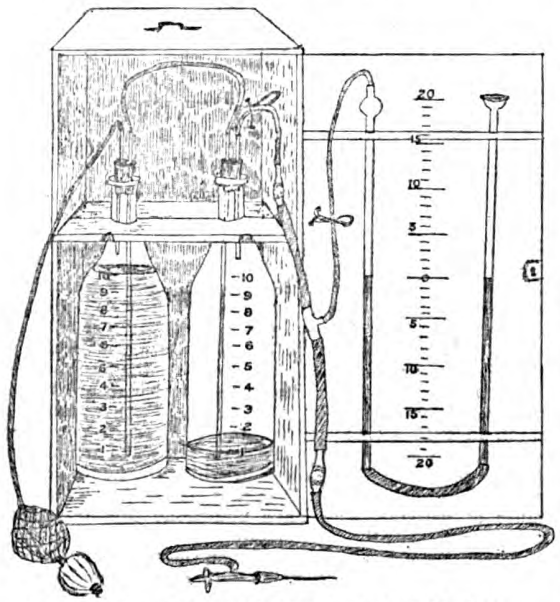
extends further than to the first or second stage of the disease.

It is an old clinical experience that immobilisation of a tuberculous lung by pleurisy with effusion can be very beneficial. Adams, West, Sömme, and Paul Brock-Martens, among many others, have emphasised this point, and L. Spengler has collected 33 cases of hydropneumothorax, of which 10 recovered, the pulmonary disease being arrested in 6. It has also been found that aspiration of a tuberculous pleural effusion is often directly harmful. Hence the conclusion that the immobilisation of the lung, if it is to be of value, must be prolonged.

Immobilisation of the lung has been attempted by a variety of means ranging from the timid strapping of one side of the chest to the drastic resection of nearly half the bony thoracic wall. No doubt these extensive plastic operations have a future before them with the present rapid advance in thoracic surgery, but their application should at present be limited to those cases in which extensive pleural adhesions exist, preventing the collapse of the lung by more conservative methods.

A method of inducing collapse of the lung which has been advocated by Murphy in America and Brauer in Europe may be briefly described, as it is still practised, and its adherents claim for it certain advantages over Forlanini's method. Under local anæsthesia an incision is made into the skin over the selected intercostal space. The muscles are separated and the parietal layer of the pleura is exposed. A blunt cannula is now passed through this layer, and when, by passing a probe through the cannula, its point is found to rest between the two layers of the pleura, it is connected with a manometer and a cylinder containing nitrogen, of which several hundred cubic centimetres are admitted. It is claimed for this open method that the risk of fatal air embolism and of wounding the lung is avoided. Strict asepsis is, however, with difficulty maintained, and a fatal case of pyopneumothorax has already been reported by Brauer and Spengler as a sequel to this procedure.

After the first operation Brauer adopts Forlanini's method



The apparatus. The water is seen standing in the manometer. The figures on the manometer scales represent centimetres. Each graduation on the bottles marks 100 c.c.

of refilling the pneumothorax with nitrogen. Forlanini's plan of introducing nitrogen between the two layers of the pleura through a fine, hollow needle, and thus inducing collapse of the lung, can now be carried out with ease in cases uncomplicated by adhesions, provided the operator carefully carries out every detail of the recently improved technique.

Technique of the Operation.

The apparatus and technique have undergone numerous modifications, and doubtless there is still room for improvement. A simple form of the apparatus is shown in the illustration.

I have tried a considerable variety of needles both on myself and on others, and have found that though the use of very fine needles is relatively painless, they have too narrow a bore to transmit the pressure within the chest to the manometer quickly enough. A thin-walled needle with large bore may be used, but such a needle buckles suddenly, as I found once to my cost. There are two needles in common use, each of which has its special advantages. Saugman's, which is of the thickness of a darning needle, has the lumen carried out to the point. The stilette can therefore be used to probe the tissues at the needle's point. The other end of the needle is connected with indiarubber tubing by a side stem. The main stem through which the stilette passes is supplied with a tap, and its opening is made to fit the nozzle of a syringe. Kjer-Petersen's differs from Saugman's needle only in this, that its point is solid, the slit-like opening being situated at one side of the needle close to its point. This needle is less liable to be clogged by connective tissue, and this is an advantage which any one who has experienced the difficulties of a first injection will fully appreciate. With this needle, however, the lung must inevitably be wounded before nitrogen can be injected, and the stilette cannot be used as a probe. Other useful forms of pneumothorax needle have been devised by Dr. S. Vere Pearson and Dr. L. Colebrook.

There is no *situs electus* for the puncture, but the point most commonly chosen is in one of the axillary lines in the seventh or eighth intercostal spaces. The operator is guided in his choice of site by the condition of the lung, his aim being to find a spot where the lung is healthiest, and to avoid the neighbourhood of cavities. As no general anæsthetic is given, a hypodermic injection of morphine is advisable half an hour before the operation. A local anæsthetic such as eucaine is also advisable.

The usual antiseptic precautions having been observed, the needle, connected with the water manometer, but cut off from the nitrogen by a clamp, is vertically thrust to the depth at which the pleura is to be found. By keeping a light hand on the needle the operator experiences a momentary sensation of resistance as the needle meets and then punctures the parietal layer of the pleura. If the point of the needle is within the blades of the unadherent pleura, and its lumen is not obstructed by connective tissue, the manometer will show negative respiratory oscillations, a typical reading being −14 cm. water on inspiration and −6 cm. on expiration. Variations of only 2 to 3 cm. on the manometer between inspiration and expiration may occur, and yet the point of the needle may be outside the pleura. When the oscillations show the mean pressure to be atmospheric, the readings being slightly negative on inspiration and slightly positive on expiration, the point of the needle is probably in the lung. If no characteristic oscillation occurs, the stilette of the needle should be used to clear it of blood or other connective tissue, care, however, being taken to close the needle quickly after cleaning, lest air be drawn in appreciable quantities into a vein.

Saugman when in doubt as to the position of the needle's point fits a syringe to the needle and aspirates. The presence of the needle's point in a vein can thus readily be discovered. On several occasions Saugman has aspirated blood, thus showing the wisdom of this precaution. Holmboe has called attention to the fact that the puncture of a vein is associated with more than the usual amount of pain, and this is a valuable warning. It is essential that the needle be carefully dried before use, as the presence of water in it is sufficient to prevent oscillations of the manometer. Blood in the needle has naturally the same effect. By adhering to the golden rule never to let gas escape into the body before characteristic oscillations are seen, the risk of fatal gas embolism is reduced to a minimum.

When characteristic manometric oscillations are obtained, filtered nitrogen or air is admitted, the quantity not exceeding from 200 to 300 c.c. at the first injection. After taking the readings of the manometer the needle is withdrawn. No dressings are required. The injections should be repeated daily, or every other day, till the lung is collapsed and a positive intrapleural pressure has been obtained.

If adhesions are absent or easily broken down, several injections of 500 c.c. each may be required before the intrapleural pressure becomes positive, but if there are extensive adhesions the pressure will rise rapidly even after as small an injection as 50 c.c. In such cases, if the adhesions do not yield to repeated injections at high pressure, it is advisable to puncture elsewhere in the hope that another pocket of nitrogen may be formed and be more efficacious by acting upon the adhesions from another point. Such cases are most difficult and require infinite patience on the part of all concerned. After laboriously injecting 100 c.c. or less, the gas may come whistling out through the puncture as the needle is withdrawn, or it may cause surgical emphysema, which leads to great discomfort if the gas has tracked up along the fascia of the neck.

Even when a most imperfect pneumothorax has been obtained and respiratory sounds are audible over the greater part of the lung, the partial immobilisation of the lung may yet be capable of giving excellent results.

The intrapleural pressure that is necessary differs according to the extent of the lung's collapse: if it is complete a positive pressure of from 5 to 10 cm. of water is sufficient, and a greater pressure is liable to cause troublesome dyspnœa. Once, when refilling a pneumothorax in which the pressure had hitherto not exceeded 8 cm., I raised the pressure to 10 cm. This was enough to cause a slight attack of dyspnœa and vertigo when the patient sat up in bed a few minutes later. A colleague who, in inducing a pneumothorax for the first time, raised the intrapleural pressure to double the desired extent by an error in reading the manometer, induced such alarming symptoms of dyspnœa that the operation had to be reversed and a large quantity of nitrogen withdrawn. When, however, the pneumothorax is strictly limited by adhesions, pressures of from 30 to 40 cm. of water or more may be employed with impunity, care being taken to use a fine needle and to strap the chest over the site of the puncture to prevent surgical emphysema.

Suitable Cases.

The selection of suitable cases for the treatment is often a great difficulty, for the indications and contra-indications have been repeatedly altered as experience has been gained by different writers. The stipulation that one lung must be quite healthy would exclude nearly all advanced cases, and yet it is in this class that so many excellent results have been obtained. Provided that the prognosis is very bad, the worse of the two lungs should be compressed even when there is considerable disease in the healthier of the two lungs. It is often difficult to estimate the degree of activity of the disease in the healthier lung, and it may therefore be necessary to immobilise the worse of the two lungs to see whether the healthier lung is a cause of the fever or not. If after complete immobilisation of the one lung the temperature remains as high as ever, the other lung is convicted of considerable active disease in the absence of laryngeal and intestinal complications. Even if such a diagnostic pneumothorax proves the other lung to be gravely affected, the question is still an open one whether the treatment should be given up or not. Personally, I am in favour of continuing the treatment; if abandoned, it is depressing to the patient, who gives up all hope; if continued, the remaining lung may yet improve, and in the course of a year or two the compressed lung may again be allowed to expand, and then, if necessary, the other lung may be compressed. Advanced tuberculous conditions of the larynx or intestine were considered as contra-indications at one time; but latterly a number of cases have been reported in which compression of the lung was followed by the recovery of tuberculous lesions of the larynx. Where intestinal tuberculosis is associated with more or less constant diarrhœa little can be expected from the treatment.

Hitherto, in Scandinavia the cases treated have been principally those in which practically the whole of one lung was involved and the prognosis was almost hopeless. Little healthy lung tissue has thus been sacrificed. But with the experience and material now at our service it seems only fair that this treatment, so successful *in extremis*, should be given a wider sphere. Murphy and Lemke have, in fact, had good results among their patients in the first and second stages of the disease, and Mjöen in Christiania has published the case of a young labourer whose early disease he checked by a few injections of nitrogen after the usual sanatorium treatment had failed. The dictum, "the unemployed of long standing are unemployable," is a strong argument in favour of a short cut to health, and an artificial pneumothorax, when supplemented by sanatorium treatment, may undoubtedly give quicker and better results than conservative treatment alone.

Before the treatment can be extensively applied to early cases of phthisis, or cases in which the disease is of old standing but of limited extent, two questions must, however, be answered. One is, What chances has the compressed lung of re-expanding when the injections cease? The other is, What are the dangers to life from gas embolism and pleural reflex? There is as yet insufficient material on which to base a reliable answer to either of these questions, and as long as this is the case many will prefer more conservative treatment.

Pleural adhesions, if extensive, prevent the formation of an efficient pneumothorax, but their existence can only be guessed at, and only repeated failures to reach a free pleural space are proof positive of their presence. In chronic disease with retraction of the thorax and displacement of the heart extensive adhesions are common, but not the rule, and even after frequent attacks of pleurisy an efficient pneumothorax may yet be obtained. Total pleural adhesion is very rare, and in a case of Dr. Jollye's, seen by Dr. Latham and myself, it has been possible to inject a considerable quantity of nitrogen in spite of pleurisy which has left basal adhesions. Forlanini at one time considered acute tuberculous disease of a lung as a contra-indication, for he held that the benefit derived from the treatment was mainly due to the removal of a disadvantageous mechanical factor by immobilisation of the lung, and that this is not sufficient to arrest the more rapid forms of phthisis. Experience has shown this assumption to be incorrect in many cases, and when early rapid phthisis is checked by the treatment, the chances of a successful recovery are even better than in the more chronic cases where the constitution has been undermined by many years of illness.

When phthisis is complicated by pleurisy with effusion good results are obtainable by replacing some of the inflammatory exudate by non-irritating nitrogen.

Treatment of Hæmoptysis by Artificial Pneumothorax.

The following case was communicated to me on July 4th, 1910, by Dr. Holmboe of Mesnalien Sanatorium, Norway, and he has kindly permitted me to publish it.

CASE 1.—A young Swede had been kept to his bed with a subfebrile temperature for several weeks, with one lung extensively involved, the other nearly normal. Even after a slight hæmoptysis followed by a further rise of temperature he refused to have a pneumothorax induced as he hoped to make a natural recovery. One night a violent hæmoptysis occurred, reducing the patient in the course of ten minutes to a state of profound anæmia and collapse. In anticipation of this the nitrogen pump with adjuncts had previously been got in readiness. The skin was rapidly disinfected with tincture of iodine, and the needle was thrust into the chest as the hæmoptysis continued. 500 c.c. of nitrogen were injected, and as the intrapleural pressure remained negative a further lot of 200 c.c. was admitted. The cough and hæmoptysis ceased at once. On the following day about half an ounce of blood was coughed up, necessitating the injection of 500 c.c. more of nitrogen, which immediately stopped the bleeding. In spite of a temperature of 104° F. the patient began to rally; no futher hæmoptysis occurred, and the temperature fell to normal. The injections are being continued, and there is every prospect of a good recovery.

The value of an artificial pneumothorax as a hæmostatic is further illustrated by the following case reported by Dr. Thue of Christiania.

CASE 2.—A workman, 32 years old, was admitted to hospital with hæmoptysis, which had lasted off and on for six days. During the following fortnight the hæmoptysis continued at irregular intervals, over one litre of pure blood, as well as much blood-stained sputum, being expectorated. The patient became very anæmic, the pulse was rapid and feeble. Both lungs were affected, but the left was much more extensively involved than the right. It was therefore assumed that the blood probably came from the left lung. A puncture was first made in the sixth space between the middle and the anterior axillary lines. No free space was found here, but a second attempt in the seventh space in the

mid-axillary line was successful, and 200 c.c. of nitrogen were injected. The hæmoptysis ceased at once, and the sputum on the following day was but slightly blood-stained. The injections were continued, and no further hæmoptysis occurred.

Hæmoptysis as a sequel to the treatment is conceivable, and it frequently happens that after the first injection, when the needle has penetrated the visceral pleura, the patient coughs up a small clot or two of blood. I have once seen a case in which profuse hæmoptysis occurred 24 hours after a vain attempt to inject nitrogen at four or five different points. Doubtless the lung was wounded more than once, but as no blood appeared at the time it is highly improbable that the hæmoptysis was due to injury of a blood-vessel by the needle's point. It is more likely that hæmoptysis was a coincidence, or that the excitement of the operation and its failure was followed by profound exhaustion which led to congestion of the lungs and consequent rupture of a blood-vessel. I have frequently noticed that violent exercise has been followed by hæmoptysis not on the same day, but early on the morning of the following day. A curious example of coincidence occurred some time ago when a colleague agreed to induce a pneumothorax in a patient whose parents withdrew their consent to have the operation performed. The day on which the operation was to have taken place the patient died from a violent hæmoptysis.

Saugman in his experience of over 50 cases has only twice seen hæmoptysis occur after the first injection. In the one case the hæmoptysis began before the treatment and continued until a sufficient number of injections had compressed the lung, when no further bleeding occurred. In the other case the pneumothorax had existed for some time, but a thick walled cavity had prevented the complete collapse of the lung. The hæmoptysis which caused death was found post mortem to come from a vessel in the wall of the cavity.

It has been shown by Bruns and Muralt among others that the blood-vessels in the compressed lung collapse, and that the anæmia in this lung is directly proportional to the pressure of the pneumothorax. The great drawback to the treatment is the uncertainty as to which lung is the seat of the bleeding, as bubbling râles due to the hæmorrhage may be heard over both lungs; but in a sanatorium where both lungs have been under observation for some time, the side from which the bleeding comes can generally be detected. To those who have stood by while hæmoptysis has continued in spite of every medicinal remedy, including the recently much vaunted amyl nitrite, this remedy will appeal in spite of its undeniable limitations.

Dangers of the Treatment.

There are a variety of dangers, such as empyema, hæmoptysis, tuberculous meningitis, and aspiration of pus from the compressed into the other lung, which may be caused by the treatment; but in practice these accidents are extremely rare. There remain two great dangers—pleural reflex and air or nitrogen embolism—each of which has claimed a number of victims.

Pleural reflex has been lately studied by Roch in connexion with an artificial pneumothorax. He induced it in animals by stimulation of the pleura by an alcoholic solution of iodine. Forlanini has obtained somewhat similar results, and has shown that the condition can be averted by anæsthetising the pleura beforehand. He therefore recommends an injection of stovaine in the neighbourhood of the pleura as a preliminary to an injection. In his analysis of 1454 thoracenteses performed in 1909 he has shown that the condition occurred four times, once only with serious consequences. Saugman, with an experience of 54 cases of artificial pneumothorax and 970 injections, has not seen one serious case of pleural reflex, and has only seen premonitory symptoms twice. He considers the absence of severe pleural reflex in his practice to be due to his avoidance of high intrapleural pressures, to his technique, and possibly also to the relatively stable nervous system of his Danish patients. His two cases of slight pleural reflex were associated with extensive pleural adhesions, which are undoubtedly provocative of pleural reflex, as they require high intrapleural pressure for their separation. Brauer has found a state of collapse follow the injection of too cold nitrogen, and he therefore warms the gas before injecting it. The operator should always be on his guard against pleural reflex, and be ready to withdraw the needle at the first sign of this condition.

Several deaths from air or nitrogen embolism have been reported in consequence of the treatment, and this accident has not been confined to first injections. In an early stage of the treatment the needle was connected with a cylinder of gas as the needle traversed the tissues. Gas embolism was therefore freely courted, and it is strange that the number of fatal cases is not greater. The improvement in technique, which includes the use of an aspirating syringe whenever the operator is in doubt as to the position of the point of the needle, has reduced the risk to a minimum, and by connecting the needle with the manometer and clamping the tube leading to the nitrogen, only the smallest quantity of gas can be drawn into a vein. Saugman estimates that at least from 20 to 30 c.c. of gas are necessary to cause fatal embolism, and such an amount is not likely to escape through the needle by accident. Brauer has reported a case in which instantaneous death followed the injection of 15 c.c. of nitrogen, but as no necropsy was allowed it is open to doubt whether death was due to gas embolism or pleural reflex. If the former hypothesis is correct it is still doubtful whether the nitrogen or inspired air entering a wounded vein was the cause of death, for it is possible, according to Brauer, that air embolism may be induced merely by the puncture of a vein which sucks in inspired air. Of the fatal cases reported, a few have had the diagnosis verified post mortem. In these death has followed sudden faintness, pallor, dilatation of the pupils with loss of reflex, facial paralysis, clonic and tonic convulsions, and loss of consciousness.

Faulty technique is probably to blame in a large percentage of the reported fatal cases, and in advanced cases of phthisis the risks of the treatment are relatively small compared with the risk of relying on more conservative methods. The risks require a more critical scrutiny, however, when the treatment is advised in cases of early phthisis with excellent chances of recovery by less heroic means.

The Choice of Nitrogen, Air, Oxygen, or Normal Saline Solution.

Atmospheric air possesses the advantage of always being obtainable, but it is absorbed more rapidly than nitrogen. Normal saline is advocated by Holmgren, who in four cases experienced greater ease in finding the space between the layers of the pleura with it than with nitrogen. Ad. Schmidt has, however, shown it to be unsatisfactory. Oxygen has also been advocated on the assumption that it would not cause dangerous gas embolism, but experiments on animals have shown this view to be incorrect.

Effect of the Pneumothorax on the Compressed Lung.

This lung may be completely immobilised if no adhesions exist, and no thick-walled cavities prevent its collapse. Such a condition rarely exists in advanced disease, the lung being usually adherent to a considerable area of the chest wall. When the adhesions are diaphragmatic or lateral, the beneficial effects of the pneumothorax are partly neutralised. Apical adhesions, on the other hand, are of little importance, as the drainage of the lung is still effective, and the partial limitation of the lung's mobility appears sufficient to arrest the disease. Such adhesions may even be of advantage as they prevent the cicatrisation of the whole lung. The patient whose lung has become a mass of scar tissue has burnt his bridges most effectively, and should his remaining lung become the seat of active disease he is helpless, whereas if his compressed lung is capable of expansion he can compress the other. Forlanini has recently reported a number of such cases of alternate compression successfully treated.

In the majority of cases the compressed lung re-expands. The compression may have lasted for several years without affecting the lung's power of re-expansion, or it may have lasted only a few months, and yet the lung has become a mass of scar tissue with a thickened fibrous capsule. The conditions which favour the latter result include complete compression of the whole lung for a considerable time, an intrapleural pressure which is kept consistently positive, and pleurisy with effusion. The nature of the inflammatory condition of the lung is also an important factor, a chronic fibrotic process being more likely to favour permanent collapse than an acute process with little tendency to scar formation. Although pleural effusion aids the compression of the lung and may render its capsule thickened and fibrotic, it frequently fails to compress the lung permanently. It is impossible to promise the patient a functionally active lung

at the close of the treatment, although the chances of its return to full activity are considerable.

Effect of the Pneumothorax on the Uncompressed Lung.

The improvement observed in this lung is often rapid. Probably the most important factor in this change is the general improvement in health which follows the immobilisation of the compressed lung.

Apart from arrest of the disease in this lung, other changes have been observed, including emphysema and elongation of the whole lung due to the increased intrathoracic pressure. Several cases have been reported in which the disease in the remaining lung progressed after the compression of its fellow. In the majority, however, the spread of the disease in this lung is certainly in spite of, rather than because of, the treatment. Carpi has shown that the opsonic index assumes a more favourable level during and after the treatment.

Minor Complications.

A serous effusion into the pneumothorax has been recorded in about one-third of all reported cases. It generally occurs within six months of the first injection, and is usually associated with fever, lasting a few weeks and falling by lysis. It seldom fills the whole pleural cavity, and it is usually sterile, although in some cases intraperitoneal injections in guinea-pigs have produced typical tuberculosis. The effusion is almost invariably of tuberculous origin, and is not due to septic infection from the lung or the site of the punctures. If the effusion is great some of it should be withdrawn and replaced by nitrogen. It is necessary to watch such cases carefully, as the fluid may be re-absorbed rapidly and the lung may re-expand and become adherent to the chest wall.

Pain is often very severe during the first two or three injections when adhesions are being stretched. Morphine may in many such cases be required. Dyspnœa is inevitable at first, but it is seldom troublesome provided the intrapleural pressure is kept within reasonable bounds. When an effusion occurs it may be necessary to withdraw a certain amount in order to relieve this symptom. The treatment often increases the frequency of respiration from 20 to 30. When the uncompressed lung is considerably involved this rate continues, otherwise it falls below the rate previous to the commencement of the treatment and in some cases is as low 18 or 16.

Tachycardia.—The pulse commonly gains in frequency at first; later, when the temperature has fallen, and the intrathoracic organs have adapted themselves to the change in position and pressure, it frequently falls to 70 or 80, rapidly rising again on provocation. When the frequency of the pulse persists, the prognosis is bad.

Surgical emphysema.—When superficial, it may be both extensive and troublesome, but it is never dangerous. By bandaging firmly over the site of the puncture it seldom spreads far. Deep surgical emphysema is far more serious, and in most cases where it occurs the leakage of nitrogen prevents the formation of an effective pneumothorax. The nitrogen may escape into the mediastinum, embracing the trachea and œsophagus. It may also extend to the submaxillary region, to the axilla, and down to the elbow. The subsequent dysphagia and the feeling of pressure in the chest are very troublesome. In such cases frequent small injections are required to avoid raising the intrapleural pressure too violently.

Dyspepsia.—This condition is, curiously enough, most frequent and pronounced in pneumothorax of the right side. Patients also suffer frequently from nausea and inability to eat much at a time. Saugman and Begtrup Hansen have called attention to the fact that marked dyspepsia and nausea are frequently precursors of a pleural effusion.

When to Discontinue the Treatment.

This is a question to which no definite answer can be given at present. Cases in which the treatment was concluded after eight months or less have frequently ended disastrously, for not only has the disease flared up again as the lung re-expanded, but attempts to re-introduce nitrogen have failed owing to extensive pleural adhesions. The danger of cutting off the patient's retreat is therefore very great if the parietal and visceral layers of the pleura are allowed to come in contact with each other again. Fortunately the pneumothorax can be maintained by refilling the pleural cavity every month or two according to the rate of absorption of the nitrogen in each case without incapacitating the patient from light work.

Value of X rays.—From first to last the X rays are of great value both in the selection of suitable cases and in controlling the results of the injections, but they are not an absolute *sine quâ non*.

Results.

Both Brauer and Saugman insist on the inadvisability of relying on a purely statistical analysis of the results, for a detailed knowledge of the gravity of each case is necessary for the full appreciation of the treatment's value. There is also great variation in the results obtained by different writers, for the selection of cases has not been based on the same principles by all. Some have induced a pneumothorax on one side when the disease has been extensive and active on both. Others have included in their statistics all those cases in which the treatment was abandoned after a few vain attempts to form an efficient pneumothorax. Laryngeal, intestinal, and renal tuberculosis have frequently caused death in patients whose compressed lungs showed no active disease at the necropsy. The total death roll, therefore, of patients who have undergone the treatment is heavy, and is liable to discourage those whose estimation of the treatment's value is based only on figures.

Holmboe has reported 2 cases, both of which were successfully treated. Thue has reported 11 cases, with good results in 5. Mjöen has reported 10 cases, with good results in 5. Würtzen and Kjer Petersen have reported 21 cases (in 7 of these no pneumothorax could be induced, and in 7 others it was strictly limited), with permanent good results in 3.

Saugman and Begtrup Hansen have reported their first 33 cases. These cases are divided into three classes.

Class 1.—Six patients in whom extensive adhesions prevented the formation of an efficient pneumothorax. The treatment was abandoned without having done any harm. The small pockets of nitrogen which were formed appear even to have been temporarily beneficial, for the temperature fell in 2 cases, bronchial respiration disappeared for good in another case, and in yet another the bacilli disappeared for the time from the sputum.

Class 2.—Three patients in whom extensive disease in the healthier of the two lungs rendered the outlook almost hopeless from the start. In one case the pneumothorax was induced in the hope that râles heard over the one lung were conducted from the other. The treatment showed this assumption to be incorrect.

Class 3.—Twenty-four patients in whom an efficient pneumothorax was induced and maintained. The majority of these improved, the improvement being permanent in 11. The causes of failure in the remaining 13 patients were as follows. Progressive disease in the remaining lung in 4, laryngeal disease in 2, intestinal disease in 4, cardiac complications in 1. In one case which was progressing favourably the pneumothorax disappeared owing to the unexpectedly rapid absorption of the nitrogen; the adhesions which formed prevented the continuation of the treatment. One patient died from secondary hæmorrhage after an operation for separation of pleural adhesions.

Forlanini in a recent lecture on the treatment does not state how many of his patients (86) were cured, but the whole tone of the lecture suggests that the results were eminently satisfactory.

Gorleston-on-Sea.

UNIVERSITY OF LIVERPOOL.—A Diploma in Ophthalmic Surgery has been established by the Council of the University of Liverpool on the recommendation of the Senate and the Faculty of Medicine. The diploma (to be styled "D.Ch.O") will be awarded after examination to candidates who possess a qualification or diploma in medicine entitling them to registration in the United Kingdom, and who have attended a three months' course of study in the anatomy, physiology, and pathology of the eye in the University, and a three terms' course of instruction in a recognised ophthalmic clinic, subsequent to qualification.

NOTES ON FOUR CASES OF PHTHISIS IN WHICH ARTIFICIAL PNEUMOTHORAX WAS INDUCED.

BY LEONARD COLEBROOK, M.B., B.S. LOND.

(*From the Inoculation Department, St. Mary's Hospital.*)

AMONG the out-patients under treatment by the Inoculation Department of St. Mary's Hospital victims of tuberculosis of one form or another have always constituted a large section, and in this section an increasing percentage of cases of pulmonary phthisis has come under treatment within the last few years.

Prior to 1909, when five wards (31 beds) in the hospital were acquired by the department for the treatment of in-patients, much hesitation was felt about the expediency of undertaking these cases, in view of the unsuitability of many of them for out-patient practice, and the difficulty of selecting these at sight. Recruited from various sources, and hence differing widely in respect of the severity of their infection, they soon created the necessity of drawing up a general plan to determine the precise mode of application of the tuberculin treatment best suited to the need of each. Not infrequently economic considerations of the individual cases have dominated the situation; for the rest the opsonic index and temperature records have been chiefly relied upon for the classification of the patients in this general plan. A few determinations of the patient's resistance to tubercle, before the commencement of tuberculin treatment, and at intervals after, have made it possible usually to decide whether or not the infection is giving rise to auto-inoculations, and to gauge, roughly, the degree of these when they occur. If evidence of these and of fever is wanting the patient continues to be treated as an out-patient, his appropriate dose of tuberculin being controlled throughout by observations of his resistance made weekly, or more frequently, as may seem necessary. But if during his period of probation, or at any subsequent time, fever or auto-inoculations are noted, he is usually admitted to the wards and subjected to a regimen of "absolute rest," combined, if necessary, with a bold exploitation of opium and allied drugs to allay cough, as recommended by Dr. M. S. Paterson of Frimley Sanatorium, with a view to ruling out auto-inoculation processes. When this procedure has attained its end and the temperature and opsonic index remain steady, the optimum dose of tuberculin is ascertained and the restricting bonds are gradually loosed before his return to the out-patient clinic. (The cases so treated, as well as those treated exclusively as out-patients, will form the subject of a future report.)

It has sometimes happened, however, that cases of phthisis thus admitted to the wards have gone from bad to worse, seeming to be beyond the pale of possible benefit by vaccine-therapy, by reason of one's inability to control the auto-inoculation processes occurring in them. Our interest in the method of induction of an artificial pneumothorax was first evoked in connexion with such cases. Despite a regimen of "absolute rest," they retained for weeks a markedly febrile temperature chart, with progressive loss of weight and of general well-being. The sputum afforded no evidence that the continued fever was due to secondary infections, and frequent determinations of the opsonic index showed that the resistance to tubercle was constantly fluctuating—from which it was inferred that even the respiratory movements of rest sufficed, with an occasional effort of coughing, to throw into the blood stream a considerable quantity of bacterial products. Such excessive and frequent auto-inoculation could be readily conceived to result in a wildly irregular succession of immunising responses and of "negative phases"—of making, and of spending, protective substances; and in addition, one must assume, in an ill-defined poisoning of the whole body, expressing itself in the phenomena of wasting, fever, &c. Inoculations of tuberculin, in doses ranging from 1/400,000th mgrm. to 1/15,000th mgrm. (bacillary emulsion), failed, as was anticipated, to influence the course of the infection.

From these considerations it appeared reasonable to expect that the *sine quâ non* for arresting the disease in such cases must be a method of splinting the lung(s), and thus checking the output of bacterial products from the focus of disease; and to this expectation two of the cases detailed below have lent substantial support. These may be now briefly described.

CASE 1.—The patient, a girl, aged 16, had had a cough six months and other ominous symptoms two months when she was brought to hospital at the New Year, 1911. She looked very ill and the thermometer registered 102·6° F. From the physical signs it was inferred that the whole of the right lung was infiltrated, with some cavity formation at the apex. There were signs, too, of older disease in the upper lobe of the left side. Examination under the X ray screen showed very marked mottling, with deficient air-entry into the whole right lung, and similar appearances, but of much smaller extent, between the root of the left lung and the apex. After five weeks of "absolute rest" the fever had only partially subsided, and tended to revert to high levels at intervals. The residual cough (after vigorous drug treatment) continued, and weight was constantly being lost. The opsonic indices were usually high, but showed rapid changes—e.g., from 1·15 to 1·46, and on another occasion from 0·98 to 1·30 within 12 hours, quite apart from injections of tuberculin. A physician by whom the case was examined was against the induction of a pneumothorax on account of the considerable involvement of the left lung. After two more weeks, however, of losing ground it was decided to attempt the collapse of the right lung. Happily in this, as in Cases 2 and 4, pleural adhesions, if present, were soft, and the first injections did not cause much distress—subsequent ones almost none. 200 c.c. of nitrogen were introduced on Feb. 28th, when the evening temperature was commonly 100° to 100·5°. The fever did not show very marked remission until a positive pleural pressure had been obtained on the fifth injection (of 800 c.c.) on March 17th; nor until about the same time was the cough decidedly diminished. Within five days of this date the maximum temperature had fallen below 99°, where it has since remained, and the cough was practically gone; it, too, has not returned in the intervening four months.

The delay here noted between the first injection of gas and a distinct change in the clinical picture affords an interesting contrast with the progress of events in Case 2, detailed below, and may probably find its explanation in the fact that, under the X ray screen, the partially collapsed lung (of Case 1) could be seen to be held up at its apex to the thoracic wall. At a later date, after a positive intrapleural pressure had been induced, this condition could not be clearly demonstrated, doubtless owing to the stretching, or breaking down, of the adhesions which formerly held up the lung.

This patient is now walking two to three miles every day without any dyspnœa, and for the past eight weeks has been slowly regaining some of the weight lost during the pyrexial period, without, be it said, the adoption of any system of over-feeding. The collapse of the right lung has been maintained up to the present by occasional injections of nitrogen, so that the left lung is still doing extra work, but at no time has this appeared to be harmful to it; on the contrary, if one may argue from the disappearance of dulness and of adventitious sounds, its condition is improved.

The future conduct of this case, as of Cases 2 and 4, to an ultimately successful issue is, however, closely bound up with the difficult question—How long is one to persist in the maintenance of the pneumothorax? which, from another point of view, may be re-stated thus: At what point in the future is re-expansion of the lung to be *allowed to occur*, either passively by the slow auto-absorption of the nitrogen, or actively encouraged by the withdrawal of the gas, without courting again the dangers of excessive auto-inoculation and toxæmia which we have all along sought to avert? With these questions in mind a kindred inquiry will suggest itself—viz., How long may a collapsed lung be expected to retain the capacity for ultimate expansion of its healthy portions?—an issue which bears, however, a degree of importance quite subordinate to the former questions, since, if the infection is finally overcome, the patient could, if need be, get through a quiet, guarded life very comfortably despite the permanent collapse of one lung.

To return, then, to the former problem (of when to refill the pleura and when to cease to do so) and its application to the patient now under consideration. After some seven injections of nitrogen the process had been stayed for five weeks; at the end of that time her temperature remained steady and

subnormal, but the gain in weight was not quite constant, and her general condition did not show distinct improvement from week to week. The stethoscope denoted the commencing return of air entry into the collapsed lung in response to slow auto-absorption of the nitrogen introduced, and one was anxious to know if such re-expansion was desirable without waiting longer for a gross warning in the way of temperature disturbance, return of cough, &c. On inquiring of Dr. C. Lillingston, who had summarised the literature of this subject, one learned that continental writers were mainly in favour of a long period (one to three years) for the maintenance of the collapse, and that *in many cases* so treated the lung did not lose its capacity for ultimate re-expansion.

To this judgment, emanating from a considerable experience, some value must be attached, but at best it seemed to be a rule-of-thumb proceeding which should, if possible, be replaced by a more precise method, having reference to individual cases and guiding the conduct of them at every point throughout the period of treatment. To this end the opsonic index was applied in this particular case as follows: Four samples of blood were collected from the patient within 40 hours, no alteration being made the while in her daily routine of gentle physical exertions; the opsonic indices of these samples showed considerable fluctuation (from 0·80 to 1·25), and from this it was argued that one must either curtail her exertions and repeat the test under conditions of "absolute rest," or else refill the pleural cavity with nitrogen, and allow her to continue getting up as before. The latter course was followed, and a parallel series of blood examinations made in the following week, with the result that the fluctuation in resistance was found to be decidedly less (0·90 to 1·10). The intrapleural pressure, however, at the conclusion of this last refilling operation, had been only slightly positive, hence it was not surprising to find after elapse of a fortnight, that there was again more definite evidence of excessive auto-inoculation, despite a steady temperature chart, and this was taken as a guide for a further injection of gas. It is proposed to continue with similar tests once a week and, later, at greater intervals, while gradually enlarging the scope of her daily exertions, until there ceases to be evidence of irregular and excessive auto-inoculations, and from indications afforded by these tests to control the further injections of nitrogen. Under Case 4 will be described a somewhat different application of the opsonic index to the elucidation of the same problem, presenting itself in a case of quite different type.

CASE 2.—This patient, a man, aged 20 years, also gave a history of six months cough and of two months evening fever (100°–102° F.). Physical signs and skiagram both pointed to infiltration of the whole of the right lung, with some breaking down at the top and involvement also of both apices on the left side, including cavity formation. As in Case 1 the opsonic index showed irregular and rapid excursions in spite of "absolute rest" and sedative drugs, and the fever continued quite unchecked. So grave did the case appear from every aspect that we did not at first think it worth while to attempt pneumothorax, but were finally prevailed upon by the anxiety of his friends that we should give him the fighting chance. On March 2nd, 240 c.c. of nitrogen were introduced into the right pleural cavity without causing very much distress. From the accompanying chart will be readily seen the effect upon the temperature. The injection was not repeated as usual on the following day on account of a little surgical emphysema which resulted, an eventuality which has been successfully prevented in subsequent injections by strapping a ball of wool tightly over the skin puncture at the end of the operation.

This man's course all along has been closely parallel with that sketched above, save that in his case the effect upon both temperature and cough was more immediate and striking. He, too, is now up and walking every day almost without dyspnœa, and a very complete collapse of the lung is maintained since the last injection eight weeks ago. Recently it was found that he had, in addition to the nitrogen, a small quantity of clear fluid in the right pleura. The explanation of this is not at once apparent to us, and at any rate it does not appear to prejudice his progress. He, too, is gaining weight, and although he retains a slight cough there has been no sputum for several weeks. The abnormal physical signs formerly present over the left lung cannot now

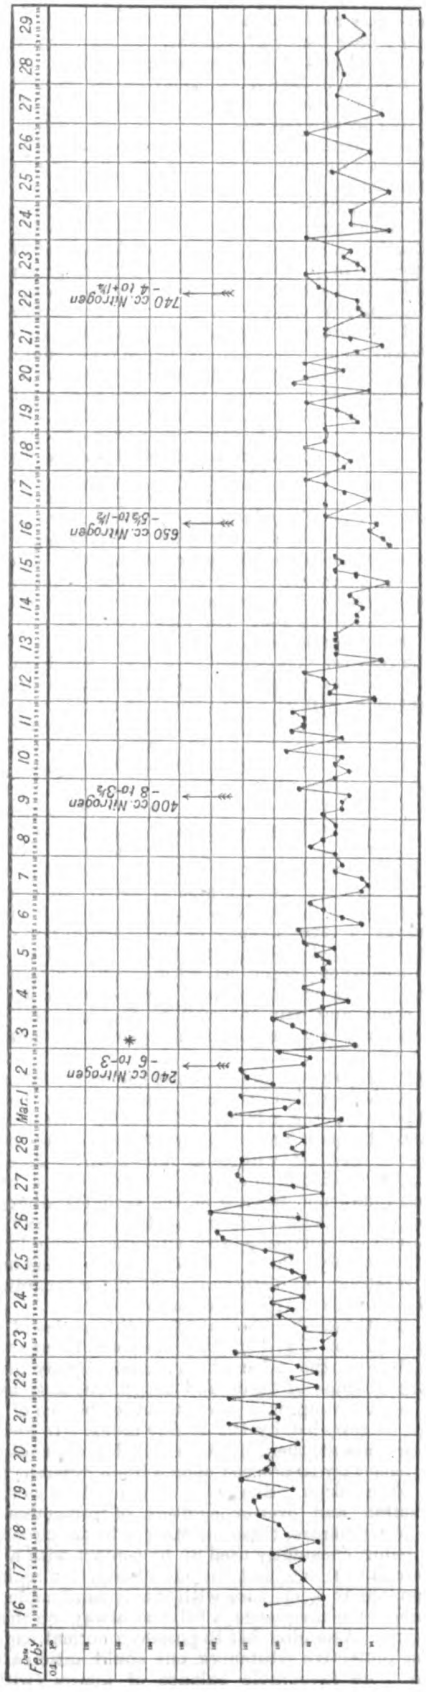


Chart of H. H. (Case 2.)
The figures against which in one instance an asterisk has been placed indicate the intra-pleural pressure (measured in cubic centimetres of water) respectively before and after each injection of nitrogen.

be determined so distinctly, doubtless in part owing to the excessive air-entry into that side.

The story of Case 3 may conveniently be set down here in series with Cases 1 and 2 on account of several features in common with them, although the attempt to induce a pneumothorax was early abandoned on account of certain difficulties not previously encountered but which are nevertheless to be expected in a considerable percentage of cases, and will not infrequently put a decisive check upon the proceedings, as in the present instance.

CASE 3.—The patient, a young man, aged 20 years, was sent to the department by Dr. W. H. Willcox, and gave a history indicating a probable duration of five months for the lung infection. On admission to hospital he presented a picture similar to Cases 1 and 2—of obstinate fever, with a fluctuating opsonic power, and rapid extension of dulness in the chest. This extension, which was confirmed by several observers independently, was mainly in the upper and middle lobes of the right lung, whereas the older dulness and the wider area of tissue impervious to the X rays were on the left side. At the outset, therefore, a new problem presented itself—on which side was a pneumothorax to be induced? Chiefly on account of the recent extension of dulness there the right side was selected. At the first operation, as well as subsequently, I was unable to proceed with confidence in the assurance that the needle-point was between the two layers of the pleura, both the mean pressure and the rhythmic variations of pressure, as recorded by the manometer, being less than I had been accustomed to see. A small quantity of nitrogen was, however, injected, and from the diminution of air-entry over the whole lung one judged that it was safely lodged in the pleural cavity, or, possibly, in a limited pocket of that cavity. Considerable pain and shock attended the injection, but soon passed off. After the third injection into the right side (still with unsatisfactory guidance from the manometer), some ten days after commencing operations, the clinical features were not appreciably altered, and examination under the X ray screen did not reveal any general collapse of the lung, hence much hesitation was felt about proceeding with this side, and the assumption was made that the lung was adherent by the greater part of its surface to the parietal pleura. In this extremity it was decided to attempt the introduction of gas cautiously into the *left* pleural cavity, in the hope that the lung might not be adherent, and that, in view of the continuance of fever in spite of some diminution of air-entry, already effected, into the right side, the desired check upon auto-inoculation might yet be obtained by collapsing the left lung. This operation was, however, attended with even more shock and pain, as well as the same technical difficulties as formerly, and in consequence has not been repeated.

In the short interval which has elapsed since the last injection the patient's condition has been approximately the same as before the first; there is no evidence of harm having resulted, and the pain produced by the injections has on every occasion subsided within a few hours. This case cannot, then, be cited for or against the principle of resting a tuberculous lung; nor, in view of the technical difficulties encountered, should it be cited against the possibility (yet to be investigated) of collapsing with advantage each lung in turn, or both partially, where extensive disease exists on the two sides, resulting in disturbances of the mechanism of immunisation such as are described in this paper.

CASE 4.—To those who have watched this series of cases the last one—that of a girl of 16 years—stands out sharply differentiated from the other three; clinically by marked cyanosis, the absence of fever and cough, but also by the persistence of a low opsonic power and the absence of auto-inoculations, as revealed by the steady index. In essaying to benefit this patient, then, by the method under consideration it was necessary to proceed upon quite a different hypothesis and expectation. She was, it seemed, a victim of under-production and over-expenditure of protective substances—in other phrase, these substances in her circulating blood were being constantly used up by contact with a large area of tuberculous tissue, and the mechanism for replacing them was unable to keep pace with the demand made upon it, there being in consequence a balance always on the side of expenditure. Assuming her to possess a normal capacity for *producing* protective substances, one could anticipate her return to a more favourable balance of affairs (with an opsonic index at, or above, normal) if means could be found to avert, in some measure at least, this excessive absorption of protective substances from the blood in its passage through the affected lung. This sequence of events it was hoped to bring about by a reduction of movements and of blood-supply through the lung when collapsed, but only in part has this hope been fulfilled.

The opsonic index showed a small but definite rise after the induction of pneumothorax—from an average of 0·60 (on a series of four estimations in the close neighbourhood of this figure), before, to an average of 0·85 (on a series of six estimations varying between 0·70 and 0·92) after; but, with or without attempts at active immunisation by tuberculin, it has been found impossible to maintain it at a level higher than this—and only twice in the course of five months has it crossed the normal line. Either the collapse of the lung was an insufficient means of cutting down expenditure, or the optimum dose of tuberculin has not yet been ascertained, or, as seems more probable, the patient has not, as was at first assumed, a normal capacity for producing protective substances in response to stimuli, natural or artificial. The extension of disease in the other lung, noted below, as well as the indifferent result obtained, in contrast to Cases 1 and 2, will most readily be explicable in reference to this latter deficiency of production.

In this case, like the first two, physical examination pointed to infiltration of the whole of one lung (left), and several observers were unable to detect any evidence of disease in the other. She had been steadily losing ground since an initial hæmorrhage four months previously. Very shortly after the introduction of nitrogen into the left pleural cavity a rub developed in the right axilla, and after three months the lesion thus betokened had advanced to a larger and definite patch of dulness.

As her general condition was not making marked progress, although not going back, I then withdrew some of the nitrogen from the left side with a view to introducing it into the right pleura. During this process of sucking out the nitrogen the border of the collapsed lung, examined from time to time under the X ray screen, could be definitely seen to approach again the thoracic wall, from which it had been separated by a wide interval for three and a half months. A very fair air-entry, too, was detected by the stethoscope, but, unhappily, with it could be heard the adventitious sounds which had been present before the induction of pneumothorax. In view of this it was judged expedient to renew the collapse of this lung for a further period, but before doing so a small quantity of nitrogen was introduced into the newly affected right side in the hope that a very partial pneumothorax might suffice to check the extension of disease there. A sharp watch was kept for signs of distress owing to the presence of gas in both pleural cavities, but these have not occurred, and the patient is now getting up and walking better than at any previous time, is gaining a little weight each week, and her colour is notably less cyanotic. During the first two months after commencing the treatment a rapid pulse-rate (100–130) gave rise to some uneasiness, being associated with frequent attacks of vomiting and faintness on getting up, but this condition of affairs cleared up with the lapse of time and the administration of large doses of digitalis. Her temperature was seldom above 99·5° F. either before or after the induction of pneumothorax, but recently it has kept more steadily subnormal.

For guidance in the problem discussed under Case 1, of when to refill the pleura with gas and when to allow expansion of the lung to occur, resort has again been had to the opsonic index—a return at any time to a very low level being taken as at once a warning and an indication for re-injection. In other cases of this type, but manifesting no deficiency in their capacity for producing protective substances, it is to be expected that the indications thus afforded would be much more clearly marked than in this case, and also that at some period of their course, if the degree of collapse was insufficient, they would manifest the phenomena of auto-inoculation characteristic of Cases 1 and 2, and that this would henceforth serve as the alternative indication for re-injection.

In view of the fact that these were all very grave cases, and that in two of them, at any rate, the rest afforded to the lung has marked, indisputably, a turning point in the infection, it would appear that the method is worthy of serious attention, and that the dangers (chiefly avoidable) inherent

in it, as well as its inapplicability to some cases, should not put it out of court for all.

The technique employed throughout for the injection of these cases has been substantially that taught me by Dr. Lillingston, to whom I am indebted for kindly undertaking the first two operations, as well as for many subsequent suggestions. It is possible that after the initial difficulties with technique encountered in the injection of Case 3 one might have proceeded to a more satisfactory issue by the method of open incision advocated by some writers.

To Sir Almroth Wright I am indebted for permission to publish these cases, and for continuous counsel during their treatment.

My thanks are also due to Dr. G. H. Orton for much help in connexion with the frequent X ray examinations of these cases.

St. Mary's Hospital, W.

A CASE OF ARTIFICIAL PNEUMOTHORAX,

PRODUCED IN TREATING CHRONIC PULMONARY TUBERCULOSIS.

BY S. VERE PEARSON, M.R.C.P. LOND., M.B. CANTAB.,

A. DE W. SNOWDEN, M.A., M.D., B.C. CANTAB.,

AND

CLAUDE LILLINGSTON, M.B., B.C. CANTAB.

THE account of the following case of pneumothorax, artificially produced and kept up by injections of nitrogen gas for the treatment of chronic pulmonary tuberculosis, should be of interest as being one of the first cases, if not the first case, produced in England with such an object. The success of the treatment has been striking, although the pneumothorax produced is, on account of adhesions, only a partial one. A brief account of a second case in which this method of treatment was attempted without success is added, and contains points of interest.

CASE 1.—Male, aged 34. Previous history: The patient originally suffered from subacute pulmonary tuberculosis affecting the upper half of the right lung in February, 1902. He devoted the greater part of the subsequent two years to his health, spending part of the time at a sanatorium in Wales, and at the end of this period he got his health well restored. He lived in South Africa for several years. In 1907 he married. He was at work regularly in the City for a year up to the autumn of 1908. Then a recrudescence of the lung trouble broke out, apparently partly due to worry connected with the illness of his wife. At the end of October, 1908, he was admitted to the Mundesley Sanatorium.

Condition in November, 1908.—Old fibrosis in the right upper lobe; recent, extending, and decidedly active infiltration and partial consolidation in the right lower lobe; recent infiltration in the left upper lobe and apex of the left lower lobe. Temperature, 99·4° A.M. and 100·6° F. P.M. rectally. Morning pulse, 90 to 100. Cough troublesome; expectoration heavy, greenish muco-pus, about 30 c.c. daily. Tubercle bacilli plentiful. Dyspeptic; well-covered, but very flabby and anæmic.

History between November, 1908, and August, 1910.—Progress was chequered, periods of improvement alternating with exacerbations of symptoms. A bad relapse with hæmoptysis started in May, 1909, just when he seemed about to be well enough to return home. His temperament was against him, for he has always been too readily depressed, too apprehensive of ill, and nervously worried. Anticipation of departure from the sanatorium contributed largely, in our estimation, to the relapse in May. After this the disease became severe in the right lower lobe, but by degrees this extension quieted down and the patient went home in December, having had a morning pulse of 78 and rectal temperatures of 96·5° A.M. and 98·4° P.M. for many weeks previously. He kept fairly well until June, 1910, when he was readmitted to the sanatorium. During June, July, and early August very slow progress was made. Pulse was always over 94, and evening temperature at 9 o'clock averaged 100·4°. The slight disease which had existed on the left side had at this time cleared up, and no adventitious sounds were audible there; in the right lower lobe softening had occurred and was occurring.

Artificial pneumothorax decided upon.—The patient was in the depths of despair, and could not contemplate months of rest in bed and endurance of feeling so ill as he did. The prospect of accomplishing marked improvement by the ordinary *régime* seemed very slight. He was getting towards the end of his tether, though not actually in an imminently grave state. At this juncture one of us (Dr. Claude Lillingston) extolled to the others the merits under certain circumstances of the production of artificial pneumothorax. This procedure was decided upon, and the first puncture was made on August 11th, 1910, in the sixth space just posterior to the mid-axillary line. It was successful in reaching the pleura. 300 c.c. of nitrogen were given on this and the following days, the highest positive pressure reaching 4 cm. of water on the manometer scale. The following injections were given at the same site each time, finishing with the highest positive pressure represented by the figure in the third column:—

Date.	Cubic centimetres of N.	*Plus* centimetres of water	Date.	Cubic centimetres of N.	*Plus* centimetres of water.
Aug. 13th	450	8	Aug. 30th	320	7
,, 15th	200	6	Sept. 4th	300	6
,, 17th	400	6	,, 7th	500	10
,, 19th	175	6	,, 12th	600	14
,, 22nd	600	11			

Between Sept. 20th, 1910, and March 6th, 1911, 18 further injections have been given by one or other of us or by Dr. W. Wynne, his home medical adviser. The amount given has varied from 175 c.c. to 600 c.c. and the pressure was gradually raised to 32 cm., and on one or two occasions to 34 cm. At the time of writing injections of about 450 c.c. are given about every fifteenth day, and the pressure is raised at each injection from about *plus* 6 to *plus* 30 or 32 cm.

Results of treatment.—The temperature dropped almost at once, the average temperature readings, August 11th to 18th, being: A.M., 97·3° F. (36·3° C.), and P.M. (highest), 99·3° F. (37·4° C.) rectally. On August 19th, 20th, 21st, and 22nd the temperature was never above 98·6° F. (37° C.). From August 24th to 29th there was a bout of high fever with a sharp pain in the right side, but without any sign of pleurisy or fluid. From the end of August, 1910, up to May, 1911, the rest temperature has on no occasion been above 98·6° F. (37° C.) rectally. The pulse became a little more frequent at first after August 11th, and then at the beginning of September gradually showed slight improvement in rate and considerable improvement in quality. Four months later it was still rather too frequent, but gradually improving.

The clearing up of the general symptoms was rapid and steady. On August 23rd the patient said, "I feel a different man." Early in September he was beginning to get up and about. By the end of the month he was walking about 1½ miles daily and by the beginning of November about 3 miles daily, which amount, or a little more, he continues to do comfortably. On Sept. 8th he remarked that it was the first morning on which he had not coughed before breakfast for many months, and the cough had almost gone altogether. By three months after the induction of the pneumothorax the cough became rare, but occasionally, about once every two or three days, generally a few days before an injection, a blob of mucoid or muco-purulent expectoration was coughed up. The expectoration used to teem with bacilli, and was green and heavy. Now bacilli are not usually found, and the sputum, when it does occur, is light in colour and consistence.

The ordinary signs of pneumothorax remain fairly constantly present over the greater part of the right chest, except that there are no definite bell note and no tinklings. Ordinary examination and that by X rays show the pneumothorax to be incomplete superiorly and posteriorly towards the vertebral column. On Jan. 2nd, 1911, the patient wrote to us saying he was "feeling very fit and well." Again, on July 7th, 1911, he writes, "I feel very well indeed all round."

CASE 2.—Male, aged 38. Years of ill-health, due to phthisis with some periods of temporary recovery, had resulted in severe chronic invalidism. From November, 1908, to October, 1910, he had been confined to bed almost constantly with slight and varying but obstinate fever—average rectal readings being about 36·9° C. (98·4° F.) A.M., to 38·0° C. (100·4° F.) P.M. Cough frequent, loose, but not

actually distressing. Expectoration plentiful (one to two medium-sized cupfuls per 24 hours), purulent, and always teeming with tubercle bacilli. The disease was bilateral, but always much more severe on the left side, where signs indicated the probable existence of extensive excavations and fibrosis with much thickening, especially basally.

Although pleural adhesions were suspected, the state was one which we thought suitable for attempting to produce a left-sided artificial pneumothorax. We all felt sure that the fever was kept up by the left-sided disease, and that the expectoration came from this side practically entirely. The lesions on the right side were comparatively slight, and this lung alone was quite capable, we thought, of supporting the patient comfortably in a quiet life, and with every likelihood of a capacity for more activity than he had enjoyed for years. Ordinary treatment had not availed to better the patient's condition materially, although it was entirely successful in maintaining a fairly good general, digestive, and circulatory condition, as well as a moderate degree of personal comfort, and in reducing the activity of the disease. He had seen the remarkable results produced by artificial pneumothorax on the patient first quoted. Although we told him that success was not assured, or even likely, he anxiously desired that the attempt should be made. Six punctures were made on two separate occasions with a Saugman needle made for us by Messrs. Allen and Hanburys. On these two occasions each of us attempted to reach the pleural cavity at different sites but without success. The punctures demonstrated that the surmise as to the pleura being thickened was correct. At one or two places it felt very thick and tough. The patient's condition eight months after the second effort at producing pneumothorax is *in statu quo ante*.

A CASE OF TORSION OF THE PEDICLE OF A UTERINE FIBROID.

BY CHARLES A. MORTON, F.R.C.S. ENG.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF BRISTOL; SENIOR SURGEON TO THE GENERAL HOSPITAL AND THE HOSPITAL FOR CHILDREN AND WOMEN; CONSULTING SURGEON TO THE COSSHAM MEMORIAL HOSPITAL.

TWISTING of the pedicle is a fairly common complication of ovarian tumour, but it is by no means so frequent in uterine myomata. In 1908 Dr. Stephen Tracey of Philadelphia published a paper[1] on a Study of Degeneration, Complications, and Associated Conditions in 3561 Cases of Fibroid of the Uterus. In only seven cases was the complication of twisting of a pedicle present. The total of 3561 was obtained from the records of 16 authors who had each contributed to surgical literature a series of 100 or more cases. When torsion of the pedicle of a fibroid does occur, it is said[2] that it may cause hæmorrhage into it, and œdema, or even gangrene, and this may lead to a fatal peritonitis. In small fibroids the tumour, it is stated,[3] may even be twisted right off the pedicle, as happens also with some ovarian cysts. Of course, the fibroid must have a fairly long pedicle to allow of this twisting. It is said[4] that at the time of twisting severe pain may be caused. It is also stated[5] that if the obstruction to the circulation is incomplete "a subacute inflammatory reaction may ensue, leading to the formation of extensive adhesions with adjacent structures, particularly the great omentum, by which the nutrition of the tumour is maintained." In my own case the fibroid was congested and hæmorrhagic, and the great omentum was loosely adherent to it. The changes were those often found in an ovarian cyst with a twisted pedicle—congestion, hæmorrhage, and dry adhesive peritonitis.

In some cases not only is the tumour rotated, but the uterus itself is twisted. A case in which this occurred is recorded[6] by Dr. S. J. M. Cameron of Glasgow. In his case the uterus was twisted so that the right tube and ovary lay to the left of the middle line. The tumour was in the same condition as in my own case—very congested and hæmorrhagic. In a case recorded[7] by Mr. A. M. Connell of Sheffield, in which the tumour itself had not undergone torsion, the uterus and appendages had become greatly twisted. The twisting of the genital organs was associated with severe pain and frequent vomiting. The abdomen was opened after symptoms had existed for 60 hours. The twisted uterus and appendages were chocolate-coloured, swollen, and œdematous, with patches here and there of a greenish-yellow lymph on their surfaces. The patient recovered.

The patient, a married woman, aged 39, was seen in consultation with Dr. W. H. Stevens on the afternoon of Tuesday, Feb. 8th, 1910. She had then had pain across the lower abdomen for nearly 48 hours. It began on the evening of the 6th and was not very severe at the commencement, so that she was able to go out after it started, but some hours later it became severe, and was so bad in the night that she could not lie in bed. There was no vomiting. The bowels had acted during the period in which the pain had been present. She had noticed a lump in her abdomen for two years; sometimes she found it in one part of her abdomen, sometimes in another, but most frequently in the right lower abdomen. Menstruation was regular but scanty. It had ceased two days before the onset of symptoms. There was no history of leucorrhœa. The highest temperature during the time Dr. Stevens had been attending her—i.e., since the onset of the pain—was 100°.

There was a mass in the left lower abdomen which caused a visible prominence there. It reached to just above the umbilicus, and as far inwards as the middle line, and outwards and downwards to the anterior superior spine and Poupart's ligament. It was too tender to handle much, but it felt hard and regular in outline. It did not move readily with light palpation. There was no tenderness at all on vaginal examination, although the abdominal tumour was so tender. The cervix was displaced much to the left—i.e., to the same side as the abdominal tumour—and to the right of it was a flat, hard mass, with a round, hard nodule projecting from it. This certainly felt like a fibroid. Nothing further was made out on rectal examination. The complete absence of the tenderness, which was so marked on abdominal examination, suggested that the mass felt per vaginam on the right of the uterus was a separate tumour. The abdominal tumour was too tender to make firm pressure on it to see if it moved independently of the pelvic one. The onset of the symptoms I have mentioned, associated with the history of some swelling in the abdomen preceding it, suggested the twisting of the pedicle of an ovarian cyst, and it seemed to me quite possible this might be the condition with which we had to deal. On the other hand, the pelvic tumour certainly felt like a fibroid, and this raised the question whether the abdominal tumour might not also be a fibroid, associated with some local peritonitis, perhaps from tubal infection on that side. The possibility of it being a fibroid with a twisted pedicle did not occur to me, for such a condition is quite rare. The hardness of the abdominal tumour might very well have been caused by tension in an ovarian cyst, due to hæmorrhage into it, from twisting of its pedicle. The fact that the patient had noticed the tumour in various parts of the lower abdomen suggested that it might be an ovarian cyst with a long pedicle, but two years was certainly a very long history for a small ovarian cyst. On the other hand, the pedicles of fibroids are seldom long enough to allow of any very extended range of movement. But patients' observations are often very inaccurate, and when we came to examine the tumour it was evident that it could never have moved very far to one side or the other.

I advised immediate operation, as the presence of an ovarian cyst with a twisted pedicle seemed quite possible, but the patient preferred to see if she got better without, as she was not then in severe pain. I did not see her again until Friday, the 11th, when she came into hospital. The pain by then had much decreased. The temperature had been between 99° and 100° each afternoon. Menstruation had come on again. The tumour was much less tender, and felt very hard, but there was a considerable amount of tympanitic distension. The condition on vaginal examination was unaltered. She had a great deal of colicky pain about

the abdomen during the night after admission, but this and the distension were relieved by hot turpentine enemata. The temperature was 99·8° in the evening and pulse 124.

I operated on the 12th. On opening the abdomen I found a little free serous fluid. The abdominal tumour was a fibroid, of the size of a cocoanut, with a pedicle an inch long, and of about the thickness of a moderate-sized finger, attached to the fundus of the uterus. It was twisted so that it required one complete revolution of the tumour to untwist it. To the tumour the great omentum was loosely adherent, and when it had been detached the surface of the tumour was found to be rough from recent exudation. It was of a purple colour, and on section was pink in colour and hæmorrhagic. It was a typical fibroid in structure. There was also another fibroid of the same size, burrowing in the right broad ligament. This was the tumour felt per vaginam before operation. The fundus of the uterus was pushed up, and to the right, and on it was another fibroid of the size of a hen's egg. I did not perform hysterectomy, as there was no evidence that these fibroids had ever caused any trouble, nor was the condition of intestinal distension favourable to such an operation. Nothing could be seen of either ovary, but in the position of the ovaries were fluctuating red masses of the size of hens' eggs. The Fallopian tube passed over the tumour on each side, and its fimbriated end was lost on the cyst wall. They were both removed and were found to be thick-walled cysts, containing material like rather liquid putty, but no hairs. She bore the operation well and made an uninterrupted recovery.

Clifton, Bristol.

A CASE OF ACUTE INFLAMMATION OF THE THYROID GLAND.

BY CHARLES W. BONNEY, M.D.

Dr. W. S. Robertson's paper on Acute Inflammation of the Thyroid Gland, which was published in THE LANCET of April 8th, p. 930, has been read by me with much interest, inasmuch as I had a case in my own practice about a year and a half ago. I have arranged to present my patient at the next meeting of the Jefferson Clinical Society in September, and had also intended to review the literature of the subject before that time. Dr. Robertson has studied it so thoroughly, however, that little remains for me to do except to report my case, which is an unusual and instructive one.

The patient was a man, 36 years old, a native of France, though long resident in the United States. He first came under observation on Oct. 4th, 1909, for a profuse nasal hæmorrhage, which was found to take origin from an ulceration of the septum. At that time it was noticed that the thyroid gland was somewhat enlarged and that the heart's action was more rapid and forcible than normal. At an examination made a few days later, after he had entirely recovered from the attack of epistaxis and its effects, it was found that a slight tremor could be elicited when our finger tips were placed together. The eyeballs also seemed to be more prominent than normal, although they did not show decided bulging. With reference to the goitre, he stated that he had first noticed it about 16 years before, while working in a mountainous district in Tennessee, where the water was said to be highly impregnated with lime salts; and, furthermore, that it had never caused him much annoyance, but that at times it would increase rapidly in size for a few days and then gradually become smaller again. Evidently the case was one of an old goitre, possibly cystic or telangiectatic, which had begun to assume the characteristics of the exophthalmic type.

On Oct. 25th, while at work, the patient was stricken with acute lobar pneumonia, the onset of which was typical, although its course was somewhat irregular. Crisis took place on the seventh day, but convalescence was disturbed within a few days by slight elevation of temperature, pain and soreness in the neck, and the redevelopment of cough, which, however, was not at all severe. Only a few days' observation was required to determine that the goitre was increasing in size. It continued to enlarge until at the end of two weeks it had displaced both sterno-cleido-mastoid muscles and completely obliterated the suprasternal notch. In the meantime the patient's general health had become much impaired. By Nov. 25th he was suffering so greatly from dyspnœa that he could not lie down; he also had considerable difficulty in swallowing, was always conscious of a sense of fulness and pressure in the head, and was harassed constantly by sharp pain in the neck, which extended down into the shoulders and arms. His skin had assumed that peculiar waxy look which one is wont to associate with malignant or amyloid disease. The evening temperature never exceeded 100° F., and was usually about 99·4°. The enlarged thyroid was hard and resistant to the touch, and the overlying skin was not in the least discoloured. A consultant who was called at this time was of opinion that the patient was suffering from a rapidly growing sarcoma and advised against operation. The question of acute strumitis was raised, but in the absence of symptoms pointing to suppuration its existence was not considered at all likely. Omitting the truly distressing details of the patient's daily deterioration I will merely state that by Nov. 30th he was suffering so excruciatingly from pressure symptoms and pain that he threatened to commit suicide unless an attempt was made to afford him relief. Against the advice of several gentlemen familiar with his case I decided to operate, and consequently admitted him to the Methodist Episcopal Hospital on Dec. 1st, and on Dec. 3rd, assisted by Professor Rodman and a member of the house staff, I operated under chloroform anæsthesia.

The so-called collar incision was made and the skin flap turned back, after which the muscles were divided and liberation of the goitre begun in the usual manner. The left lobe was freed without much difficulty, but the right one was so firmly fixed, and apparently so intimately connected with the superjacent, lateral, and subjacent tissues, that sharp dissection was begun in order to liberate it. A few strokes of the scalpel were followed by an issue of pus, the exact source of which, however, was not immediately determined. The wound was surrounded with gauze and forceps passed into the opening from which the pus was oozing, whereupon the flow became copious. Several ounces, certainly eight or ten, came out. When the flow had apparently nearly ceased I passed my finger through the aperture from which it was coming and swept it around the walls of a large cavity into which it found its way, thinking thereby to bring forth any remaining thickened collections of pus or tissue débris. This manœuvre was followed by a tremendous gush of blood, which must have resulted in exsanguination of the patient had it not been quickly controlled by packing the cavity whence it issued with long and thick strips of gauze. A few seconds only were sufficient to show that pressure forceps and clamps would avail naught in stopping the bleeding, so packing was at once resorted to; as it was the patient lost a large quantity of blood. It would seem that the entire left lobe of the thyroid had become converted into an abscess cavity, and that when the wall of the latter was broken down by my exploring finger both arterial and venous vessels poured out their contents into it.

The patient was taken back to bed as soon as possible, and although his condition was critical for a few hours he reacted well and eventually made a good recovery. The packing was not removed until the fourth day. No hæmorrhage followed its removal. Pus was discharged from the wound for a number of weeks, and after it had stopped a thin brownish fluid was discharged for awhile before closure finally took place. The last of this fluid was seen on Feb. 2nd, 1910.

A culture of the pus which was taken at the operation gave a pure growth of pneumococci. Dr. Harlan Shoemaker, who examined the culture, endeavoured to reproduce the organisms, but they did not grow satisfactorily. He stated that their vitality was reduced and their virulence probably attenuated.

Philadelphia.

ANTIVACCINATIONISTS ON THE INCREASE.—At a meeting of the Garioch district committee held on June 24th it was stated in the report of the public health subcommittee that the medical officer had reported that the number of statutory declarations of conscientious objectors under the Vaccination (Scotland) Act, 1907, was increasing at an alarming rate, and might lead to a serious epidemic in the event of an outbreak of small-pox.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RÖTHELN WITH ANGINAL THROAT, FOLLOWED BY FATAL PURPURA HÆMORRHAGICA.

BY ERNEST STRATFORD, M.R.C.S. ENG., L.R.C.P. LOND.

GERMAN measles is so frequently regarded as a slight and unimportant ailment that I feel impelled to record a recent unpleasant experience, in the hope that it may lead to a more serious view being taken of this condition by other practitioners.

The patient, a boy aged 3½ years, had previously been healthy; there were no other children in the household. When first seen on May 17th there was a well-marked confluent rötheln rash on the face and chest, normal and characteristic except in severity. The temperature was 105·5° F.; the throat was congested, and the tonsils were enlarged. Treatment: hyd. c. cretâ (gr. i.), simple fever mixture, and formamint lozenges. On the 19th the temperature was 105°. The tonsils were enormous, with a yellow slough on one; rash was present all over the body. This condition lasted for three days. As the tonsillitis was so severe and as the child had ceased to accept formamint, I injected diphtheria antitoxin (3000 units). The left tonsil sloughed away; the right remained enlarged two days later, but was clean. The temperature was still 104°. On the 23rd the rash had commenced to fade and had entirely disappeared by the 26th (nine days from appearance), except for staining. The temperature, however, remained between 104° and 105°, and the right tonsil was persistently inflamed. In view of the relative failure of antitoxin I prescribed sodium salicylate (7 gr.) and tr. ferri perchlor. (5 min. t.d.s.) on the 26th. On the 30th the child's nose bled and hæmatemesis occurred, being treated by ice and cold applications. On June 1st the temperature was down to 101°; the tonsil was still large but softer, but there was profuse hæmorrhage from the nose and gums. Both feet were œdematous and there was hæmaturia; no albumin or tubal casts were found, but large quantities of red corpuscles were seen with the microscope. Calcium lactate (15 gr. t.d.s.) was prescribed, but owing to frequent hæmatemesis the amount absorbed was uncertain. On the 4th numerous purpuric petechiæ appeared on the legs, body, and face. On the 5th I was called urgently in the morning and found the child blanched; pulse 140, feeble. Two large clots were removed from the nostrils, the petechial spots were increased in number, and nearly pure blood was passed per urethram. Owing to another urgent case I was unable to get to the child again until the evening, when I took two pints of normal saline with 1 in 2000 adrenalin chloride, intending to inject intravenously; the child had unfortunately died five minutes before I reached the house. Post mortem, bleeding continued from the nose for 12 hours, and numerous large subcutaneous ecchymoses appeared on the upper surface of the body, whilst the sugillations were very extensive.

There was an epidemic of a very mild type of rötheln in the town, and there were cases in the same road. The rash, enlargement of concatenate glands, &c., were typical though abnormally severe, as was the tonsillitis. But the purpuric eruption coming on after the fading of the rash, accompanied by epistaxis, hæmatemesis, and hæmaturia, to my mind makes it clear that it was a case of purpura hæmorrhagica sequential to what one might call "malignant" rötheln. One is not surprised to find purpura associated with malignant morbilli or variola, but I can find no record of its association with rötheln, nor have I seen rötheln accompanied by so severe a tonsillitis. The text-books at my disposal, including Osler, make no mention of purpura as a complication of rötheln, and, indeed, most of them dismiss the disease as an almost negligible ailment. A doubt has entered my mind as to whether there could be any connexion between the antitoxin injection and the purpura, but I have never seen anything more than an urticaria follow much larger doses. I shall be glad to hear if any fellow practitioner has had a similar experience.

Wellington College Station.

NOTE ON A CASE OF FRACTURE OF THE THYROID CARTILAGE.

BY ELSIE M. ROYLE, M.D., D.P.H. VICT.,
ASSISTANT MEDICAL OFFICER, CITY OF LONDON INFIRMARY, CLAPTON, N.E.

THE patient in the following case, an old woman, 74 years of age, was suffering from chronic bronchitis and emphysema. She was up and dressed, and went into the lavatory on April 11th, 1911, about 6 P.M.; while stooping down over the water-closet pedestal she slipped and caught her chin on the edge of the seat, and was unable to rise. She was found immediately after in this position kneeling on the ground, with her chin ledged on the seat, and was assisted to rise by a nurse, after which she was able to walk back to her bed. Ten minutes later she was seized with the most urgent dyspnœa. The eyeballs were prominent and staring, and the expression was anxious; the chest moved but little with respiration, the patient complaining of pain in the right side of the throat. Dyspnœa gradually increased, and in spite of the administration of stimulants the pulse began to grow feebler. It was evident that there was laryngeal obstruction, and that a serious injury to the thyroid cartilage had occurred. Hence tracheotomy was performed without an anæsthetic, since it was not deemed safe to administer one; breathing improved for a short time, but the patient gradually sank and died about an hour after the operation.

An inquest was held, and the post-mortem examination revealed a horizontal fracture of the right ala of the thyroid cartilage. Hæmorrhage had occurred beneath the mucous membrane and a hæmatoma extended from the site of fracture along the right aryteno-epiglottidean fold on to the false and as far as the right true vocal cord, obstructing the glottis almost completely. The chief interest of this case is the somewhat unusual nature of the accident and the fact that the laryngeal obstruction developed gradually, coinciding with the spread of the hæmorrhage beneath the laryngeal mucous membrane.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Lymphadenoma.—The Part Played by the Upper Air Passages as Avenues of General Infection.

A MEETING of this society was held on July 5th, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. D. CHALMERS WATSON demonstrated a man, aged 41, suffering from Myasthenia Gravis. The patient was a paraffin worker, and had been getting gradually weaker since the beginning of the year. Pains throughout the body had lasted six weeks. The clinical condition was characteristic of the disease.

Dr. G. LOVELL GULLAND showed a man suffering from Locomotor Ataxia who had greatly benefited by injections of salvarsan.

Mr. CHARLES W. CATHCART showed a woman, aged 40, after operation for Gall-stones complicated with Cyst in the Head of the Pancreas. For 15 months she had had frequent attacks of abdominal pain, sickness, and jaundice. The gall-bladder contained several stones, the common duct had none. A cyst of the size of a walnut was found in the head of the pancreas. The gall-bladder and pancreatic cyst were drained through the anterior wound and a good recovery was made.

Dr. GEORGE A. GIBSON showed: 1. A man, aged 41 years, who complained of Uneasiness in the Chest and Breathlessness on Exertion. His vessels were healthy, diastolic arterial pressure 92, systolic 133, pulse regular and equal, heart slightly enlarged, long late systolic thrill continued beyond second sound, harsh murmur through similar period, also separate aortic diastolic murmur. Skiagram showed no shadow above that of the heart more than normal. The

diagnosis was that of patent arterial duct with aortic disease. 2. A patient admitted with Purpura in the fifth year of syphilitic infection. A fusiform dilatation of the aorta was diagnosed. A great reaction ensued on the injection of salvarsan followed by left hemiplegia. The arterial pressure throughout never exceeded 90 diastolic and 140 systolic.

Dr. GULLAND and Dr. A. GOODALL described a case of Lymphadenoma treated with salvarsan. The case was a typical one, occurring in a man, aged 25 years. Employment of all the usual remedies had failed completely to ameliorate the condition. There was a remarkable although temporary improvement in the temperature and condition of the glands following intravenous injections of salvarsan. There was a gradual failure to improve on repetition of the injections and death followed. Dr. Gulland believed that if treatment had been commenced at an earlier date cure might have been effected.

Dr. A. LOGAN TURNER opened a discussion on the Part Played by the Upper Air Passages as Avenues of General Infection. He said that this subject must necessarily be of intense interest, not only to the general practitioner, but to the specialist in every branch—to the public health official and to the pathologist and bacteriologist. This gateway was prone to infection because as respiratory passages, and over a limited area as part of the alimentary canal, they were open to both air and food infection. Both in health as well as in catarrhal conditions of the mucous membranes of individuals apparently in perfect health micro-organisms were constantly present. These organisms varied in number, in vigour, and in pathogenicity, whilst the tissues of the host might undergo a diminution in resisting power, or fresh organisms might gain entrance, and bacteria previously quiescent or avirulent might become active and give rise to acute infection. In the mucous membrane of the upper air passages there was a well-developed lymphatic network and free communication by efferent vessels with the cervical lymphatic system, and through it with the blood stream. Many experimenters had shown that a general blood infection might readily follow the smearing of the pharyngeal mucous membrane with the streptococcus. The pathways of infection from this area were numerous: (*a*) the lymphatic ring with the naso-pharyngeal, faucial, and lingual tonsils and the lymph nodes of the pharynx all communicated with the cervical lymphatic system, and thence with the blood-circulating system; (*b*) the venous channels connecting the upper air passages with the central nervous system; (*c*) the lower air passages in direct continuity, and hence inhalation infections; and (*d*) the œsophagus in direct continuity, and hence ingestion infection.

A. *Infection of the cerebro-spinal system.*—(*a*) The pyogenic organism. The occurrence of meningitis, sinus thrombosis, and brain abscess secondary to suppuration of the nasal and accessory sinus cavities and of the middle-ear cleft was well known, yet there were many cases—e.g., lateral sinus thrombosis—in which the primary source of infection was overlooked. This was even more true in connexion with suppurative disease of the posterior ethmoidal and sphenoidal air sinuses, because the nasal discharge might have been too insignificant to call for remark. In the majority of cases of accessory sinus and ear disease the infection had spread by continuity of the inflammation through the contiguous bony walls, the latter becoming carious or completely absorbed. Infection might also take place through the venous channels which effected a communication between the upper air passages and the interior of the skull. A careful inquiry by Dr. Turner into the possibility of infection by way of lymphatic channels had led him to the conclusion that proof of the same was still wanting. (*b*) and (*c*) Pneumococcal and influenzal meningitis. It had been conclusively shown that these inflammations might arise as a direct infection from the upper air passages. Many observations might be quoted to show the occurrence of the meningococcus in the naso-pharynx not only in patients suffering from this disease but also in those in contact with them and who must be regarded as carriers. The investigations of Westenhöffer and Lingelsheim had demonstrated that the naso-pharynx was a more frequent portal of infection than the nasal cavities and accessory sinuses. If these facts were accepted, by what pathway did the organism reach the meninges? The part played by the lymphatic vessels was still open to discussion. Possibly in some cases infection might pass through the sphenoidal sinus and thus reach the meninges, but Hirsch had raised the question as to whether the middle-ear cleft might not sometimes be the route of infection, and thence through the labyrinth and internal auditory meatus. This suggested that the labyrinthine deafness of cerebro-spinal meningitis might not always be secondary to the meningitis, but that it might possibly precede it. As to acute poliomyelitis, Flexner considered that all the theoretical conditions required to establish the naso-pharyngeal route of infection had been supplied by experiment. It had been shown that naso-pharyngeal catarrh was very prevalent in communities in which poliomyelitis existed. Wickham had called attention to the lymphatics as the route of infection. With regard to tuberculous meningitis, Weigert believed that the nasal and post-nasal cavities and their lymphatic tissues formed the usual gateway of infection in tuberculous meningitis. The existence of tubercle bacilli in the healthy nose, their presence in adenoid vegetations and in middle-ear disease, the occurrence of primary nasal tuberculosis as a more common affection in children than was formerly realised, together with the close proximity of the nasal and cerebral cavities, all pointed to the upper air passages as a frequent portal of infection.

B. *Infection of the lungs; pulmonary tuberculosis.*—Dr. Turner asked in what proportion of cases were the lungs infected by the inhalation of the tuberculous virus or through the cervical lymphatic system from inoculation of the mucous membrane of the upper air passages. As to the lymph drainage of this area, the whole of that belonging to the nasal, naso-pharyngeal, and pharyngeal mucous membranes passed through the deep cervical glands into the large veins at the root of the neck and thence to the right side of the heart and pulmonary artery. The tracheo-bronchial glands received their afferent vessels from the mucous membrane of the trachea, bronchial tubes, and pulmonary alveoli. The efferent vessels from these glands terminated in a broncho-mediastinal trunk which opened into the large veins at the root of the neck. No inter-communicating lymphatic vessels had been demonstrated either between the inferior deep cervical glands and the tracheo-bronchial glands, or between the latter and the deep cervical glands. Hence anatomically a descending tuberculous invasion from the cervical to the peribronchial glands or an ascending infection from the latter to the cervical glands was not possible. There was clinical evidence, however, that the deep cervical (supra-clavicular) glands could be affected from the mediastinal glands. In experiments inoculation of the mucous membrane of the upper air passages with tuberculous virus was followed by infection of the cervical glands and the development of pulmonary tuberculosis. Could they always determine the cervical glands as the path of infection to the lungs? Three pathways were possible—inhalation, ingestion, and the cervical lymphatic system. Tubercle bacilli might be present in lymphatic glands without producing any histological evidence of their existence. Once the lungs had become the seat of tubercle the tonsils and cervical glands might be secondarily infected from the tubercle-laden sputum. Dr. Turner asked in what proportion of cases of tuberculous cervical glands did pulmonary tuberculosis develop. In his own experience it was rare to find this lung affection developing in connexion with primary tuberculous disease of the nose and pharynx. In cases of laryngeal tuberculosis secondary to pulmonary phthisis one did not detect enlarged cervical glands. If one granted the cervical lymph glands as avenues of infection how did the tubercle bacilli pass from them to the lungs? The view that the apex of the pleura and lung was directly infected from the cervical glands had been strongly opposed. In the absence of any direct lymphatic connexion between the cervical and bronchial glands, tuberculous infection of the lungs by way of the cervical glands could only take place through the large veins and the right side of the heart. Albrecht had formulated the view that the primary site of infection was most often in the lung from inhalation. If the cervical glands were also tuberculous, it was secondary to the pulmonary affection, either from secondary infection of the pharynx through the sputum or by an ascending gland infection from the peribronchial glands upwards.

C. *Infection of joints and bones.*—(*a*) Acute rheumatism. The possibility of the throat as the portal of infection in this disease had been much discussed. Many writers had described an acute inflammation of the tonsils as preceding

the joint affection, and Poynton isolated from the tonsil the same organism as he had obtained from an endocarditis, pericarditis, and arthritis. Valvular inflammation might precede an arthritis or the latter might occur independently. Gürich cured 98 out of 125 cases of articular rheumatism by removal of the tonsils, which in many cases appeared healthy, yet in the crypts inspissated secretion was found, and it was asserted that the rheumatic pains were caused by the toxins absorbed from the organisms in the crypts. (*b*) Suppurative affections of joints and bones; that pyogenic infection of these might enter through the upper air passages must be held as proved, and Dr. Turner cited cases in proof, as one case of osteomyelitis which occurred three days after an acute tonsillitis, and where the staphylococcus aureus was cultivated from both the tonsil and the abscess.

D. Infection of the intestinal canal.—Appendicitis; the relationship between this disease and tonsillitis had been frequently discussed, the blood being considered the pathway by some authors, the gastro-intestinal canal by others. The appendix with its lymphoid tissue had been regarded in its healthy state as performing a function similar to that of the faucial tonsil, and it was reasonable to suppose that both were liable to inflammatory attacks, and Sutherland had asked whether such impairment might not be due to the rheumatic virus.

E. General septic infections.—These might be due to latent inflammation of the naso-pharynx, and attention to this might be the means of curing obscure cases of continued fever.

Dr. R. W. PHILIP said that in the case of scarlet fever or diphtheria the primary manifestations occurred in the throat, and such facts as these had led him to study the tonsils as the channels of infection of the tubercle bacillus. It was necessary to begin such a study in the child. His view was that the tubercle bacillus might enter the system practically at any point in the respiratory or alimentary tracts, but most likely at that point where these two tracts crossed one another. The mucous membrane in the child was particularly absorbent and owing to faulty hygiene and dirty habits it was always in a more or less devitalised condition. It was rare to find enlargement of the extra-tonsillar glands and when so enlarged it was due to tuberculous invasion. This was shown by the next step in the progress—namely, that the glands at the lower level began to enlarge until they formed a fan-like arrangement of glands in the triangular region, and from this a subsequent invasion of the lung apex took place. These clinical stages had been traced in the experimental feeding of guinea-pigs, an apical pleurisy resulting with a passage of tubercle directly to the lung. It was not the large suppurating glands which were dangerous, but the small cervical tuberculous glands which allowed the tubercle bacillus or its toxins to pass to the apex of the lung and thus demonstrated the immense importance of paying attention to the state of the teeth.

Mr. E. SCOTT CARMICHAEL said that anatomically the glands were arranged in three sets in the neck: (1) those round the spinal accessory nerve; (2) those immediately under the posterior belly of the digastric muscle; and (3) those close to the border of the internal jugular vein. During the first year of life the first group was most often affected, the infection generally spreading from the Eustachian tube and the middle ear or mastoid. It was well, therefore, to perform the radical mastoid operation, for almost always there was extensive tuberculous disease. Almost every one of these occurred in bottle-fed babies. The glands of the second group received their lymph supply from the tonsil and they were found affected in children over a year old. The tonsils were small and showed no external evidence of ulceration, tuberculosis commencing in them at the bottom of the crypts. He asked if they were not justified in removing these tonsils in every case whether they were enlarged or not. One gland infected another, and hence he advocated the removal of all three groups. He could not agree with Dr. Philip as to the direct infection of the apex of the lung from tuberculous glands in the neck. He had dissected many such cases of advanced glandular disease and had found no affection of the apex.

Dr. J. S. FOWLER said that the small enlarged glands were very common in the necks of children, but there was very little post-mortem evidence that they were tuberculous in nature. These glands were present in from 30 to 40 per cent. of all children

Mr. CHARLES W. CATHCART said that tuberculosis in joints must have been carried by the blood, and therefore the anatomical relation between glands and lung did not amount to very much. Tuberculosis of glands was seldom associated with tuberculosis of the lung. He always felt that in merely excising the glands of the neck one had not done one's entire duty, and he was in the habit of always giving directions for the treatment of the tonsil. The lymphatic glands were a natural protection and had great power of recuperation; it was therefore only necessary to clear away those glands which were definitely affected, and he thought that this was a safer procedure than enucleation of all the glands.

Dr. THEODORE SHENNAN said that the retro-pharyngeal gland drained the posterior part of the nasal cavities. It was very difficult to find these in adults, and he wondered if they escaped infection in some way. He thought that infection of the meninges from the naso-pharynx might occur in children through the petroso-squamous suture which was not closed at this period. He had noted that the lymphatic glands at the root of the right lung were much more frequently affected than those of the left lung. Was the absence of visible tuberculous affection of the tonsils proof that they had not been the means of transit of the infection? In cryptogenic pyæmia one always examined the tonsils, and a hidden abscess in the bed of the tonsil might be present.

Dr. CHALMERS WATSON referred to infections of a general nature which had been cured by excision of the tonsils.

Dr. JAMES MILLER thought that a thorough microscopic examination of the tonsil gave much more reliable information than inoculation experiments. The organism of bovine tuberculosis had never yet been found in the lung, though it was present in the cervical glands, and this was a point against the theory of transference of infection from glands to lung.

Dr. GEORGE WILSON (New Zealand) referred to the widespread gonococcal infection of the nose amongst the Maoris and Samoans. This spread up the tear sac and gave rise to an inflammation of the eyes exactly similar to trachoma. The disease was spread by the habit of nose-rubbing.

Dr. GEORGE HUNTER, Dr. A. D. WEBSTER, Dr. H. M. CHURCH, Dr. J. EASON, Dr. T. M. BURN-MURDOCH, Mr. J. W. DOWDEN, and the PRESIDENT also took part in the discussion, and Dr. TURNER replied.

GLASGOW AND NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETIES.

Operative Treatment of "Procidentia."

A COMBINED meeting of the Glasgow and North of England Obstetrical and Gynæcological Societies was held in Glasgow on June 16th and 17th, Dr. A. W. RUSSELL, the President, being in the chair.

Professor J. B. HELLIER (Leeds) introduced a discussion on the Operative Treatment of "Procidentia." He said that he had chosen a very practical subject—the surgical treatment of the commonest of gynæcological conditions, but one which, in his opinion, required elucidation. The subject of procidentia was a wide one and presented many phases for discussion, but he asked the Fellows present to focus their attention on the one question, "What method of treatment gave the best results as regards the permanent cure of the condition?" Professor Hellier first considered the chief difficulties of the problem. The uterus was in whole or in part outside the vulva, and in a position of retroflexion or retroversion, so that the first part of the problem was to secure the uterus in a position of ante-version or flexion. Secondly, he pointed out that in procidentia the uterus was hypertrophied, the enlargement being due to elongation of the supravaginal cervix, to the body of the uterus itself, and to the enlargement of the labia cervicis, especially where there were old-standing lacerations. These uterine conditions, in his opinion, required attention during the operation for the radical cure. Thirdly, he pointed out the prolapsed state of the vaginal walls—cystocele and rectocele—and urged that no operation was of any use where these conditions were left untreated. He referred to the changes taking place after the

menopause, and showed how such changes caused a procidentia or made an existing one worse. The most serious difficulty, he said, was the effect of further child-bearing on cases that had been operated on. He doubted if there was any operation that was free from risk or difficulty in a labour following or where relapses would not occur. The best results were obtained after the menopause or where sterilisation was performed. He thought sterilisation justifiable in patients over 40 years of age, but not in young women. Regarding the operative treatment, he advised a combination of operative measures. Fixation of the uterus without the plastic operations was useless. Vaginal hysterectomy did not cure the condition. Professor Hellier then described his own surgical procedure in such cases. A flap of mucous membrane is resected from the anterior vaginal wall, the width of the flap depending on the size of the cystocele. The bladder is pushed well up and out of the way. The utero-vesical space is packed with gauze, the peritoneum being not yet opened. Amputation of the hypertrophied cervix is then performed. The gauze is now removed from the utero-vesical pouch, the peritoneum opened, and the fundus uteri brought into the vaginal wound. The appendages are inspected and partial salpingectomy performed. Catgut sutures are then passed through the anterior uterine wall and through the cut vaginal edges at each side. They are then tied. The remainder of the vaginal mucous membrane is closed by a continuous catgut suture. This continuous suture may take up some of the anterior uterine wall. The last step is to perform a colpo-perineorrhaphy. In doing so Professor Hellier recommended building up a good perineal body and stitching the edges of the levator ani muscle together. Continuing, he stated that from 88 to 90 per cent. were cured, in 5 or 6 per cent. the results were not up to expectation, and 5 per cent. showed some degree of failure. In concluding his interesting paper Professor Hellier gave the results obtained by other operators.

Dr. W. L. REID (Glasgow) thanked Professor Hellier for his valuable and interesting address. He reviewed briefly the different operations he had performed for procidentia. In his earlier days he removed the uterus in whole or in part, but soon gave up that operation as the results were so unsatisfactory. Fair success could be obtained by the Alexander-Adams method, but relapses were common, especially in those who were not careful of themselves. In cases of procidentia at the present he always performed anterior colporrhaphy and a colpo-perineorrhaphy by Lawson Tait's method. During these operations he urged that a strictly aseptic technique was essential to obtain a good result. In most cases he thought the plastic operations were sufficient, but in some cases where the uterus tended to come down again he advised a ventrofixation even in view of all that had been said against it.

Dr. D. LLOYD ROBERTS (Manchester) advised anterior, lateral, and posterior colporrhaphies. In performing these operations he always aimed at extreme narrowing of the vagina as he found the canal sometimes after operations tended to become dilated again. He strongly objected to the removal of the uterus in such cases, as there was always a tendency later to prolapse of the small intestines, and also objected to shortening of the round ligaments. The hypertrophied cervix he left alone because after the restoration of the uterus to its normal position the cervix, relieved from irritation and traumatism, diminished quickly. Only in exceptional cases did he perform ventrofixation, as it often caused pain and difficult urination.

Dr. JOHN CAMPBELL (Belfast) divides his patients requiring operative treatment for procidentia into three groups —viz.: (1) Those who are still in the child-bearing period of life; (2) those beyond the child-bearing period, but who are still strong and active; and (3) those who are old and frail and unlikely to stand a major operation. For Group 1 he performs amputation of the cervix where necessary, anterior colporrhaphy and colpo-perineorrhaphy, and round ligament suspension (Gillian's operation). For Group 2 he performs the same vaginal operation as Group 1, together with a ventrofixation, and in Group 3 he performs colporrhaphies so as to tighten the vaginal canal as much as possible.

Dr. ROBERT JARDINE (Glasgow) said he understood Professor Hellier to say that the operation should never be done on a woman who might bear a child. He agreed with this. He condemned fixation of the uterus in a woman who might become pregnant on account of the difficulty which would most probably arise during labour. He had seen six cases of labour after this operation, and in only one was delivery of a living child possible through the natural passages. Cæsarean section or craniotomy was necessary in the others. Sterilisation of a young woman in his opinion was not justifiable, and the operation of ventrofixation for procidentia should only be performed after the menopause.

Dr. A. DONALD (Manchester) said that he had performed anterior and posterior colporrhaphy in at least 500 cases. He had found those measures satisfactory in that he did not find it necessary to open the abdomen either by laparotomy or by the vagina. He thought the operation described by Professor Hellier as suitable for cases of prolapse in women past the menopause was too severe and was not necessary, inasmuch as excellent results in these cases could be obtained by colporrhaphy. The operation of colporrhaphy was safe; it gave no trouble at a subsequent confinement, and even the subsequent confinement did not always destroy the result of the operation. The colporrhaphy, he said, must be done thoroughly and the vagina must be contracted high up.

Dr. W. BLAIR BELL (Liverpool) expressed cordial agreement with Professor Hellier in regard to the prevention of procidentia. He entirely disapproved of any operations such as the Dührssen-Martin-Mackenrodt (or Schauta-Wertheim, as Professor Hellier called it) in sexually functional women who never ought to be sterilised for such a procedure. It was bad surgery, he thought, to operate on cases where ulcers of the vaginal walls were present. He always performed extensive anterior and posterior colporrhaphies and fixed the uterus by a modified Gillian's operation. In some of his cases pregnancy had occurred but no relapses had taken place. Sometimes he performed ventrofixation in cases where the round ligaments were useless.

Professor J. A. C. KYNOCH (Dundee) thought that all mutilative measures should be avoided, as they were dealing with a condition which was a source of discomfort and not of danger. Any operation in a child-bearing woman that involved fixation of the uterus should not be performed, and sterilisation of such women he held was not justifiable. In child-bearing women he performed an extensive anterior colporrhaphy and a colpo-perineorrhaphy, and, if necessary, amputated the cervix. In women after the menopause he performed a ventrofixation and also the vaginal plastic operations. He had performed the operation that Professor Hellier had described, but his experience of it had been too recent to express an opinion on the late results.

Dr. J. M. MUNRO KERR (Glasgow) stated that he was opposed to abdominal fixation of the uterus except in exceptional circumstances. He had only once seen trouble follow at a subsequent parturition, but still he thought the treatment crude. He specially referred to the treatment of fixing the uterus between the bladder and anterior vaginal wall which had been so fully referred to by Professor Hellier. He had performed the operation in chosen cases, but in two of his own cases a serious pelvic inflammation supervened. This inflammation was due, he thought, to the fact that it was extremely difficult to cleanse the field of operation and also to the presence of blood which became infected.

Dr. W. E. FOTHERGILL (Manchester) had noticed that, after treating prolapse by anterior colporrhaphy and perineorrhaphy, those cases in which the uterus remained retroverted after the operation generally recurred, while the prolapse did not return in cases in which the anterior colporrhaphy brought about anteversion. In performing anterior colporrhaphy he removed a very wide portion of mucous membrane. This brought together in front of the cervix the parametric and paravaginal tissues, with the result that the cervix was forced up and back into the hollow of the sacrum.

Dr. G. BALFOUR MARSHALL (Glasgow) said no operation had been devised to cure all cases. An abdominal fixation alone was of no use. In cases of prolapse he always performed anterior and posterior colporrhaphies with the Gillian round ligament operation and ventrofixation of the uterus in women over 40 years of age. He considered a simple colporrhaphy useless to cure a cystocele. He agreed with Dr. Fothergill in that the colporrhaphies must be extensive. In cases associated with hypertrophy of the cervix he was of the opinion that amputation was necessary.

Dr. C. OLDFIELD (Leeds) said that plastic ope-

were sufficient, but an additional support and a more permanent result could be attained by adding vaginal or abdominal fixation. He performed a vaginal fixation in fat women with a large cystocele and a retroflexed uterus, but never before the menopause. In patients who were robust and under 50 years of age he performed a ventrofixation with the vaginal plastic operations. He had injected quinine solution into the base of the broad ligament in one case and found the immediate result good.

Dr. SCOTT CARMICHAEL (Edinburgh) said that a vaginal fixation was, in his opinion, the best operation for the cure of cystocele. Abdominal fixation was unsatisfactory. He had experience of 20 or 30 cases and believed that the operation of vaginal fixation was a good one. He only performed it in women who were over 40 years of age, although he thought there was little risk in future child-bearing. In complete procidentia he stated that hysterectomy after Mayo's method gave good results.

Dr. ARNOLD W. W. LEA (Manchester) said that in women during the child-bearing period posterior colporrhaphy gave good results, but if the uterus were much enlarged a better result was obtained by supplementing a fixation of the uterus. He thought the cervix should be amputated when necessary. In old women he removed the uterus and at the same time performed extensive anterior, lateral and posterior colporrhaphies. In his 28 cases he had had no relapses. Wertheim's vaginal fixation, in his opinion, was not a good operation.

Professor MURDOCH CAMERON (Glasgow), Dr. T. B. GRIMSDALE (Liverpool), and the PRESIDENT also took part in the discussion.

Reviews and Notices of Books.

A Text-book of Gynæcological Surgery. By COMYNS BERKELEY, M.A., M.D., B.C. Cantab., F.R.C.P. Lond., M.R.C.S. Eng., Gynæcologist and Obstetrician to the Middlesex Hospital, Senior Physician to the City of London Lying-in Hospital, Surgeon to In-patients at the Chelsea Hospital for Women, &c.; and VICTOR BONNEY, M.S., M.D., B.Sc. Lond., F.R.C.S. Eng., M.R.C.P. Lond., Assistant Gynæcologist and Assistant Obstetrician to the Middlesex Hospital, Senior Surgeon to Out-patients at the Chelsea Hospital for Women, &c. With 392 figures in the text from drawings by Victor Bonney and 16 coloured plates. London: Cassell and Co., Limited. 1911. Pp. 720. Price 25*s.* net.

IN this work, extending over some 700 pages, the authors record their experience during their various years of service at the Middlesex Hospital and the Chelsea Hospital for Women. The book contains but few references to the operative work of other surgeons, and the opinions expressed are those of the authors alone. The result is a very clear and detailed account of all the common operations of gynæcology. The illustrations from drawings by Mr. Victor Bonney, mainly diagrammatic, are numerous and good, although, in common with all illustrations of operative procedures, they suffer from the fact that the reader must of necessity discount the apparent simplicity with which they depict the most complicated and difficult procedures, a fact which need not in any way detract from their value as diagrams.

The details as to the preparation of the patient and operations in private houses are valuable and good; the position of the operator, however, on the right of the patient when she is in the Trendelenburg position is not nearly so convenient in the experience of many as is that on the left. All the various operative procedures are very fully described, and although there are details with which operators would not unanimously agree, yet with the main part of the authors' teaching we are in entire accord. The important question as to the relative value of sub-total and total abdominal hysterectomy for fibromata of the uterus is fully discussed, and the authors decide in favour of the former operation. There is room for another opinion. It is true that the total operation is perhaps a little more difficult, but the latest statistics show that the results of both operations are practically equally good in the hands of sound operators. The question of the value of an operation must be decided by the results obtained by the best operators, and viewed in this light the danger of the two operations is practically the same. As the authors do not recommend vaginal drainage, they naturally do not approve of drainage through the vagina after total hysterectomy, but their statement that in total hysterectomy more or less septic infection occurs is not borne out by the results obtained by those who practise this method in cases of fibroid tumours of the uterus. That sepsis occurs when total hysterectomy is performed for cancer of the uterus is no doubt a fact, but that it is usual for stitches to be discharged by the vagina after this operation for fibroid tumours of the uterus is not in accord with the experience of many surgeons. If total hysterectomy has been properly performed, and practically none of the vagina removed, as should be the case when operating for benign conditions, the puckering that the authors mention does not occur to any extent, and the scar rarely gives rise to any pain or trouble.

A chapter is devoted to the operation of utriculoplasty, a procedure which probably will not live, and for which many observers see no need. Wertheim's extended operation for cancer of the uterus is very fully and lucidly described, and if there are any surgeons who still require conversion to the necessity for performing this operation in all operable cases of cancer of the cervix uteri, we would recommend to them a perusal of this section. A very clear account of the various steps of the operation is given with good illustrations, and there is a complete discussion of the important question of the removal of the glands as a routine step of the operation. We notice that the authors apparently do not recommend a subcuticular suture for the skin, a method which may give even a better scar than Michels' clamps which they favour.

This is a good book, and because we may expect to see future editions of it we point out places where we think its teaching might be modified. In the section on ligatures the authors unhesitatingly condemn the use of catgut, an opinion to which they will find many opponents; nor do we think that the use of biniodide of mercury for vaginal douching is to be preferred to lysol, which is not mentioned. We are also surprised to find in considering drainage, that drainage through the abdominal wound is preferred to that through the pouch of Douglas, a recommendation which we should hardly have expected. The chapters on after-treatment and the nursing of the patient contain a great deal of information and are very sound. At the end of the book are given the general results, not the authors' only, of the operations carried out at the Middlesex Hospital and the Chelsea Hospital for Women for the period January, 1905, to August, 1910. The whole work forms a manual of much value, which certainly will be of great assistance to the young surgeon, and will be read by the experienced operator with interest.

Convergence in Evolution. By ARTHUR WILLEY, D.Sc., F.R.S. London: John Murray. 1911. Pp. 177. Price 7*s.* 6*d.* net.

Dr. Willey, previously to his recent appointment to the McGill University in Montreal, spent several years in the tropics investigating animal life; and the present volume is the result of some of his studies and leisurely reflections. It is therefore noteworthy that, though the reflections doubtless emanate from an armchair position, they are based upon much first-hand acquaintance with animals in the field. Many persons have written and are writing glibly of the problems associated with, for instance, the colours of animals, who have not actually observed whether the instances which they

give, and which they have evolved out of inner consciousness tempered by museum specimens, fit the environment. This is by no means good enough for Dr. Willey, who is a sympathetic observer as well as a competent weaver of observation and theory into a harmonious narrative. We are acquainted with leaf-like insects, such as the well-known Kallima butterfly; but fewer persons are aware that there is a leaf-like fish known technically as Platax vespertilio. This fish has the habit of floating idly on its side, and the details of its colour and marking, as well as the thinness of body implied by the floating habit, conspire to produce the suggestion of a leaf. But a leaf floating in the sea might, perhaps, not be regarded by all of us as one of the likeliest objects to meet with. Dr. Willey, however, remarks that in the mangrove-fringed oceans of the East such leaves are actually common, and he adds that a bifacial leaf is "one of the commonest objects, dead or alive, ashore or afloat, in nature." It is precisely here that we can see for ourselves how necessary it is for the describer of such facts to have viewed them in their actual and everyday surroundings. Quite other views of the leaf-like fish would commend themselves even more did we not realise that leaves are no rarities where the fish occurs. A considerable chapter deals with this and other allied phenomena known as protective resemblance, mimicry, and so forth. A perusal of this chapter renders it clear that Dr. Willey is, on the whole, in agreement with what are, perhaps, the prevailing theories on these matters.

Dr. Willey, however, is by no means in accord with the recent bold and unconventional views of Dr. Gaskell upon the alleged origin of vertebrated animals from arthropodous creatures, such as scorpions, trilobites, and the like. It is, indeed, with this "earthquake hypothesis"—as Dr. Willey terms Dr. Gaskell's very exciting views—that the present volume really chiefly deals. And hence, indeed, the title. For what Dr. Gaskell and those who agree with him term points of real resemblance are only, according to Dr. Willey, instances of convergence. There is no doubt that convergence does lead of itself to resemblances so close as to deceive even the elect among morphologists. The confusion in the popular mind between snakes and worms is an example to the point. In both limbs have disappeared and a vermiform body has resulted. It is rather by dwelling upon such instances that Dr. Willey attacks Dr. Gaskell than by criticising in detail the arguments of that eminent physiologist. For as Dr. Willey also points out, at least in effect, we have to readjust our canons of criticism before we can satisfactorily grapple with Dr. Gaskell's comparison of the thyroid gland of the larval lamprey with the uterus of the scorpion.

In order to render this line of criticism more effective, Dr. Willey has collected together a number of very striking cases of convergence, of which there can be but little doubt that they are true cases of convergence. These are largely and naturally highly technical, and appeal rather to the experienced anatomist than to the general reader. Thus, the remarkable discovery by Dr. Alcock of the formation of milk for the nourishment of their young in certain shark-like fishes is treated of. As was known to Aristotle, certain members of the shark tribe bring forth their young alive instead of following the prevalent and nearly universal habit among fishes of laying eggs. But it used to be pointed out that the analogy with the mammalia was very small, since there was no formation of any organ to act as intermediary between the mother and the fœtus. Dr. Alcock, however, has found that in the Sting Ray and some others the oviduct of the ray produces bundles of projecting villi which penetrate in masses the gill clefts of the young, and pour into the œsophagus an abundant secretion of a milk-like fluid which serves the developing fœtus for nutriment.

The analogy between such facts and the formation of "pigeon's milk" has not escaped Dr. Willey, who recapitulates the observations of the illustrious John Hunter upon a milky fluid formed in the crop of pigeons in the breeding season. All these very various examples of convergence and parallelism so largely drawn upon by Dr. Willey not only have resulted in a very entertaining book, but prove to us how careful the naturalist must be in deducing family relationship from even the most apparently obvious points of resemblance.

Biblisch-talmudische Medizin. Beiträge zur Geschichte der Heilkunde und der Kultur überhaupt. Von Dr. JULIUS PREUSS, Arzt in Berlin. Berlin: S. Karger. 1911. Pp. 753. Price, paper, 20 marks; bound, 22 marks.

THE Talmud is essentially a law book and embodies the fundamental code of the Jewish civil and canonical law. It is composed of the Mishna, which contains the text, and the Gemara, which is a complement to it and a commentary on it. There are two Talmuds—the Babylonian and the Jerusalem. The Mishna and the Babylonian Gemara together are called the Talmud, and the date of its origin is from the second to the sixth century B.C. There exist no purely medical writings from the older Jewish times—not even any on natural history—comparable to those of Pliny. The oldest Jewish recorded literature begins with the Pentateuch or Thora, and this and the Talmud alike are books of the law; medical affairs therefore occur only incidentally in so far as they relate to the codex of the laws—ritual, civil, and canonical. There is consequently no medicine of the Talmud in the sense in which we speak of Egyptian, Hellenic, or Roman medicine. The Talmud, however, contains copious references to the popular medical conceptions of its period, "folk-medicine," but there is no systematic arrangement of the subjects mentioned, and such views as are set forth bear a strong impress of Hellenic medicine. The author gives an account of the following subjects so far as they occur in the Bible and Talmud:—The Physician and other Members of the Healing Profession; Parts of the Human Body, including their Anatomy, Physiology, General Pathology, and Therapeutics; Injuries, comprising Surgery; Diseases of the Eye, Teeth, Skin, Ear, and Nose; Nervous Diseases and Madness; Gynæcology and Midwifery, Materia Medica, Forensic Medicine, Hygiene, and Dietetics. The author has grouped and classified the scattered and copious references under the above headings. Finally, there is a bibliography containing the chief writings on medical matters in the Bible and Talmud.

This work—which must surely have been a labour of love—we might almost say a "kolossal" work—is the first ever published by a physician on Biblical and Talmudic medicine, and it has been compiled direct by the author from the original sources. It appears that Wunderbar, a layman, finished his work on the same subject in 1860. The only other works on pure Talmudic medicine are the collection of excerpts of Rabbinowicz (Paris, 1880) and the writings of Bergel (Leipzig, 1885). All the more, therefore, are we indebted to the author for his brilliantly written, clearly expressed, compendious work. To anyone interested in the history of medicine it will prove indispensable. The author has compared Jewish medicine with the healing art as it flourished in Greece, Rome, and Alexandria, and he has given particularly full notes of the references to the authorities cited. He, moreover, chooses to put a very modest judgment on what must have been a laborious yet fruitful series of literary researches, published, as he says, on the twenty-fifth anniversary of his "promotion" to the degree in medicine. He characterises himself in the words of a compatriot, Rabina, "Ich bin nur ein Sammler und Ordner" ("I am only a collector and methodiser").

The general introduction on the Physician and his Associates, or attendants, is most readable and singularly interesting. To the practice of the art of surgery the Jewish physician was a stranger. Unlike the Roman and Grecian surgeon, his Jewish *confrère* never had to deal with the injuries resulting from the application of judicial torture, nor had he much to do either with gynæcology or midwifery—two departments practically left to women. Women were usually examined by women, and the physician was only called in in exceptional cases or when artificial help was urgently needed in labour. Military surgeons do not appear to have existed in early Jewish times, nor have we any information as to the course of study involved, though it is plain that many of the Prophets had some medical skill—e.g., Elisha—while Abraham was commanded to circumcise his own son. The physician was an instrument as it were in the hand of God. Still, like every other human being, he had his own free will, and laws were propounded as to the responsibility of the physician, and in cases of proved neglect of duty he was held responsible. The physician was an educated man, while those who let blood—called ummân—were regarded as workmen and stood far below the former in the social scale, and to be called "Schröpfer" or "Schröpferin"—i.e., a "cupper"—was a term of insult. There is an interesting account of circumcision, an operation which Zippora, the wife of Moses, performed on her own son. The names of two midwives have come down to us from the period of the Egyptian slavery, Schiphrah and Pu'ah, who were commanded to kill all the firstborn of the Israelities. According to the Talmud, these were Jochebed, the mother of Moses, and Miriam, her daughter.

Interesting comments are made on the different parts of the human body. Take the hand, for instance. When a child comes into the world its hands are closed, as if it held the whole world as its possession; when man makes his exit the hand is open, to show that he possesses nothing which he can take with him. The hand was raised in taking an oath, and the practice we are told is derived from God himself. Interesting information is given regarding the growth of the nails and the practice of allowing them to grow uncut under certain conditions—e.g., in sorrow. Nebuchadnezzar not only "did eat grass as oxen, but his nails were grown like birds' claws," as described by Daniel. The number of bones in the body is given as 248. Such knowledge of anatomy as they had was chiefly obtained from the slaughter-house and the sacrifices. There is a picturesque account of the eye made well worthy of reading by sprightly comments and useful references. The secretion of the nose was regarded as injurious, and there is much that is interesting regarding sneezing. Has not Sir Jonathan Hutchinson recorded that he never saw a patient who was severely ill sneeze?

Every single organ of the body is fully, lucidly, and piquantly dealt with. There is a long account of castration, circumcision, and allied subjects, of stone in the bladder and other diseases, including the various "pests" and plagues. As only animals that were without spot or blemish could be used as an offering, the most minute instructions are given in this regard. A lamb with a double ear would be eligible under certain conditions (p. 333) for sacrifice, but congenital or acquired deformities disqualified for the priesthood. An interesting account is given of the practice of putting rings in the ears, and of the significance of this act. There is a full account of epilepsy, and other common nervous conditions were recognised, and the interesting comment is made that only five cases of suicide are recorded in the Bible.

The chapters dealing with dietetics, hygiene, and the prevention of disease are very elaborate, and many trite and useful maxims applicable to-day might be culled from them. The basis of the whole system is that the care of the body is a religious duty. Any sudden change of diet or excess is hurtful. The clearest descriptions as to what is "terepha"—meat from animals that have suffered injuries—and what is "Kash er" or "Kosher" are laid down. Much stress is laid on personal cleanliness and disinfection, such as washing of the hands before and after eating or after micturition or defæcation, and the use of the bath for menstruating or lying-in women is described. The curious belief that the cessation of the menses in pregnancy was due to the fact that the blood is changed into milk is noted—we believe this rather natural idea had a wide vogue. Suckling the offspring is regarded as a duty on the part of the mother, and it was often continued for nearly two years. A wet-nurse was substituted only very exceptionally.

There is not a dull page in the book, and we have the greatest pleasure in strongly commending the perusal of this unique, compendious, and most instructive treatise on "Biblical-Talmudic Medicine," which more than justifies its subtitle as a "Contribution to the History of the Healing Art and to Culture in General."

Das Radium in der Biologie und Medizin. By Dr. E. S. LONDON, Director of the Royal Institute of Experimental Medicine, St. Petersburg. Leipsic: Akademische Verlagsgesellschaft. 1911. Pp. 199. Price 6 marks.

THIS treatise, by the well-known Russian authority on the therapeutic and biological action of radium, contains details of his experimental work as well as a *résumé* of the various articles that have appeared in the medical and scientific press since the discovery of radium some 14 years ago.

The author discusses the mechanism of radium irradiation on the living tissues, and especially Schwartz's theory of its destructive action on lecithin, and Löwenthal's hypothesis of the action of the emanations as consisting of the activating of organic ferments. Chapters follow on the action of radium on bacteria, on ferments, toxins and antitoxins, on plants and the lower animals. Of even more interest is the description of experiments showing the influence of radium on development, and the production of teratological changes in the embryo. The various organs of the body may be arranged in series according to their sensitiveness to radium irradiation. First the nerve cells; then the lymphoid tissue, the generative glands, the liver, and the spleen; then follow in order the kidneys, the suprarenal capsules, muscle, cartilage, and blood-vessels; and last of all, the parotid, the pancreas, and the mucous membranes. Quite infinitesimal doses of radium bombardment produce a definite physiological action on the skin. London himself found that a closed capsule containing 18 mg. of radium produced a permanent reddish-brown patch of discolouration on the skin after an exposure of only 15 seconds. He calculates that the weight of the radium B. corpuscles producing this definite physiological effect was less than 0·000,000,000,0005 gramme. The author quotes a number of authorities who testify to the analgesic action of radium in neuralgia, epithelioma, iridocyclitis, gout, and even tabes.

The historical chapter on radium-therapy begins with an account of Strebel's treatment of lupus in 1900. This is followed by accounts of the work of Goldberg and London of St. Petersburg, Exner of Vienna, and Macintyre in this country; and is completed by reference to the recent work of Dornensci, Wickham, and others. There are a number of illustrations of microscopic preparations showing the effect of radium irradiation on the various tissues. The work is completed by a table of the literature of the subject, which includes a list of 250 papers, of which seven are contributions from the author.

In conclusion, Dr. London expresses his matured opinion

that radium has already won for itself an assured place in the treatment of superficial diseases of the skin and mucous membrane, and he hopes that the radium emanation will attain an equally definite place in the treatment of acute and chronic diseases of the internal organs.

Cholera and its Treatment. By LEONARD ROGERS, M.D. Lond., F R C.P. Lond., F.R.C S. Eng., B.S. Lond., Major I M.S., Physician, Cholera Wards, Medical College Hospital, Calcutta; Professor of Pathology, Medical College, Calcutta; Fellow of the Calcutta University. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 236. Price 10*s.* 6*d.* net.

OF the many works on the subject of cholera the one under review by Professor Leonard Rogers of the Indian Medical Service is surely one that will well repay the earnest study of practitioners in the East. The author at the commencement cites a quotation from another Indian authority on the disease—C. Macnamara—to the effect that it would seem as if the profession in India had almost abandoned itself to despair in the matter of treatment of cholera. This, although true at the time these words were written, cannot be said at the present time; and our author can lay especial claim to having devised what is probably the most successful method up to the present time of treating this fell disease.

In the first chapter we find an account of the history of cholera epidemics and the lessons learnt from them. This is illustrated by some excellent maps. The author, in the preparation of this chapter, acknowledges his indebtedness to Macnamara's classical work on the History of Cholera. The various views of the authorities of the time are quoted, showing what differences of opinion have existed as to its etiology. The author, in relating with reference to Koch's discovery how the English Government sent an eminent bacteriologist to India to investigate Koch's conclusions, states rightly that he reported at that time against Koch's views, but we do not find any mention of the fact that this authority, in the last editions of his work on "Micro-organisms and Disease," distinctly states therein that the organism of Koch *is* the cause of the affection. Professor Rogers next deals with the epidemiology of cholera, its seasonal incidence, and its relationship to meteorological conditions; also with the seasonal incidence in the different Provinces of India. We then come to the important subject of its etiology and prophylaxis. This chapter is very complete, embracing, as it does, the whole subject of the discovery of Koch's organism.

Dr. D. Cunningham's researches are detailed; then Pfeiffer's test, the great discovery of the phenomenon of agglutination by that pathologist, gives by far the most reliable method of recognising the specific organism of Asiatic cholera. Next we come to the matter of the recognition and isolation of the comma bacillus in cholera stools, followed by a description of its morphology and cultural peculiarities; the indol and hæmolytic reactions, the resisting power of the bacillus, the duration of the specific bacillus in the stools after attacks of cholera, the subject of cholera carriers, the degeneration of cholera bacilli in artificial and natural conditions, and, lastly, the toxins and antitoxins produced, all receive their due meed of description. The author then enters on the important subject of prophylactic inoculation against cholera. Concerning this, the evidence in its favour is certainly not to be gainsaid, but, strange to say, it appears that, owing to the severity of the reaction after the dose of Haffkine's vaccine which is required to produce lasting immunity, there is now a nearly complete abandonment of his method in India without anything better having been substituted for it. Considering the evidence of the statistics produced by Haffkine, Powell of Assam, and others, the abandonment is incomprehensible. We now come to the mode of infection of cholera. The facts showing how it is spread through food and water, flies, and soiled clothes are laid stress on; the good effects of the disinfection of wells by permanganate of potash are shown, and then we come to the predisposing causes, such as chills, fasting, visiting endemic areas, race, sex, and age incidence. The author evidently does not agree with the evacuant treatment of the disease advocated by the late Sir George Johnson; the writer of this review, however, during his career in India employed practically no other, and without prejudice he concluded that his rate of mortality compared very favourably with those following the treatment by opium. It is also somewhat surprising to find Macnamara advocating the latter treatment, although he himself narrates how during an attack of the disease that he went through in Calcutta he took castor oil himself with eminently satisfactory results. The chapter detailing the clinical description could not be improved upon—it is excellent; the remarks on diagnosis and prognosis are likewise extremely helpful.

Succeeding the clinical description comes the account of the post-mortem appearances. Here the description of the changes in the heart might have been given more fully. Johnson well pointed out how, in the stage of collapse, these differ remarkably from those found in the stage of reaction, the appearances found bearing striking evidence to the truth of his theory of choleraic collapse. The state of the blood is well described. The last chapter is devoted to the subject of treatment. The methods advocated by Annesley, Corbyn, Twining, Johnson, Morehead, Macpherson, Goodeve, Macnamara, Wall, and Kenneth Macleod are narrated; and then we come to the most valuable detail in the work—to wit, the author's system of treatment. The main principles of this are the administration in the stage of collapse of a hypertonic saline intravenous injection of sufficient amount to raise the blood pressure to normal; and secondly, the free administration by the mouth of oxidising agents to destroy the toxins in the gastro-intestinal tract. Rogers never gives opium, we are glad to see, when once the rice-water stools have appeared. The success of this treatment is well shown by the latest statistics published, in which he had the low percentage mortality of 23·3.

Professor Leonard Rogers has made all medical officers serving in the East his debtors by this admirable work.

Atlas der Kristallformen und der Absorptionsbänder der Hämochromogene. Eine für Physiologen, Pharmäkologen, und Medizinalbeamte bestimmte Studie. Von WALTER J. DILLING, M.B., Ch.B. Aberd., Ersten Assistent des Institutes für Pharmäkologie der Universität Rostock. Mit einem Vorwort von Professor KOBERT. With 34 plates. Stuttgart: F. Enke, and obtainable from F. Bauermeister, Glasgow. German text, pp. 71; English text, pp. 65. Price 29*s.*

IT seems that the germ of this beautiful and useful monograph must be sought for in the class-room of Hoppe-Seyler more than 30 years ago, when that distinguished physiological chemist remarked to Professor Kobert (to whom the work is fitly dedicated) that "hæmochromogen was for the majority of the medical faculty the least known derivative of the blood pigment, but that it would, nevertheless, gain more and more importance both in theory and practice." And so it has proved. A purely pharmacological study of coniine and its related alkaloids led to researches on crystalline forms, absorption bands, and the mode of formation of a whole series of substances which all belong to the hæmochromogen group. After a short historical introduction on blood pigment and its derivatives the author figures the

spectroscopical characters of hæmochromogen and its crystalline preparations obtainable from blood by the action of pyridine, piperidine, and their derivatives, from hæmatin, and from hæmols by various other reagents. The net result of a very elaborate and painstaking research is that the crystals that are produced from blood and hæmatin by the use of the various pyridine and piperidine bases are crystals of true hæmochromogens. The plates are excellently got up and will prove most valuable, not only to pharmacologists and physiological chemists, but also to teachers of forensic medicine. The cost of the work was defrayed by the Carnegie Trust, and we congratulate both Professor Kobert and the author on the successful investigation of a subject with such wide practical and theoretical connexions, both in chemistry and in medicine. The text is printed both in German and English, while Professor Kobert contributes a short preface.

Lehrbuch der Augenheilkunde in der Form klinischer Besprechungen (*Text-book of Diseases of the Eye in the form of Clinical Lectures*). By Dr. PAUL RÖMER, Professor of Ophthalmology and Director of the University Eye Clinic at Greifswald. With 186 illustrations in the text and 13 coloured plates. Berlin and Vienna: Urban and Schwarzenberg. 1910. Pp. 1028. Price, paper, 20 marks; bound, 22 marks.

IT has been said of a certain learned professor that his lectures to students consisted of excerpts read from the proof sheets of the proximate edition of his text-book. Professor Römer has inverted the process and published a text-book which consists of verbatim reports of his lectures. Neither method of economising labour is to be commended. Systematic lectures have usually in the past been so tiresome, arid, and futile—with, of course, some notable exceptions—that they have deservedly fallen into disrepute; but surely they must have reached their nadir when they were culled from even the most excellent text-book. Scientific lectures, on the other hand, if they fulfil their object, are so often laden with verbiage, so full of repetition and emphasis, and so devoid of the elements of literary style, that if they are allowed to retain their pristine form of delivery they must of necessity fail to conform to the canons of a good text-book. Professor Römer's book shows signs of careful revision and reconstruction of the actual lectures, so that an orderly exposition of the subject is presented to the reader, but in spite of these attentions it still remains a hybrid product, failing to exhibit the excellence which doubtless characterised the lectures when they were delivered, and still more completely failing to reach the standard which should be aimed at in a students' text-book.

The style of such a book as that under consideration is peculiarly irritating. It is full of redundancies similar to that of the opening sentence—"Gentlemen, we must commence the term's work with the study of diseases of the conjunctiva and cornea." Typical cases are described in the language in which they were demonstrated to the class, and "meine Herren" are instructed to observe the peculiarities which are hidden from the ken of the less fortunate reader. Anon the author ceases to be a lecturer and lapses into text-book style, much to the relief of the reader. There is really a splendid text-book contained in the work, but it is difficult to see the wood on account of the trees. Yet if the student has patience to plod through this forest of a thousand closely printed pages of German we cannot but feel that he will be sufficiently rewarded. Doubtless most of the information could be gathered by less arduous means, but there are some topics that nowhere else have we seen treated so well and so authoritatively. Dr. Römer has acquired a wide reputation for his work on immunity and has proved himself a worthy and indefatigable pupil and disciple of Ehrlich. We strongly recommend those who have not the time or energy to read the whole book to peruse the chapters on conjunctivitis, hypopyon ulcer of the cornea, and sympathetic ophthalmia. There are few ophthalmologists who will not thereby obtain useful information not so readily acquired otherwise.

In our opinion the work will prove most useful to teachers of ophthalmology, but only advanced students of the subject can be recommended to add it to their libraries. There are no ophthalmoscopic plates.

LIBRARY TABLE.

Medical Homes for Private Patients, 1911. A Classified Directory, with Lists of Medical Consultants. Edited by RICHARD BINNIE. Alphabetically arranged. London: The Scientific Press, Limited. 1911. Pp. 150. Price 6*d.* net.—This paper-covered booklet will undoubtedly prove of service to the practitioner in enabling him at once to find out what private homes, sanatoriums, or health resorts are available for any particular case. There is, first, an alphabetical index to the different counties, under which the various institutions appear grouped according to their purposes. Next follow lists, alphabetically arranged under the names of the towns in which they are situated, of medical, surgical, and nursing homes; children's, convalescent, and accouchement homes; homes for chronic and incurable cases, for drug abuse, inebriety, nervous and mental diseases, for Weir-Mitchell and rest-cure treatment, electrotherapy, massage, or Nauheim treatment, consumption sanatoriums, institutions for supplying trained nurses to the public, and health resorts. There are also lists of medical men, arranged alphabetically and followed by their private addresses and the names of the hospitals to which they are respectively attached, the utility of which is very doubtful. For the public such lists may be misleading, for the medical profession they are unnecessary. The book concludes with a list of the principal European health resorts.

The Refraction of the Eye, a Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S. Eng. Fifteenth edition. London: J. and A. Churchill. 1911. Pp. 275. Price 5*s.* net.—A book which has reached its fifteenth edition since publication in 1884 needs little reviewing. So great success is given to few authors in this branch of literature. Among the many monographs on refraction Hartridge's is *facile princeps* as an introductory exposition of the subject. The student's path is made smooth and pleasant, and the hills are skilfully engineered so that none of the gradients are steep. Not a single algebraical formula puts in an appearance to cause the most timid wayfarer a moment's apprehension. And so the goal is reached in Chapter XII. on Spectacles. There are things which might be omitted—for instance, that hardy annual the strabismometer.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the cooperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., E. A. MINCHIN, M.A., F.R.S., and GILBERT C. BOURNE, M.A., F.R.S. June, 1911. London: J. and A. Churchill. Price 10*s.* net.—This issue contains only three memoirs: (1) Cortical Cell Lamination of the Hemispheres of Papio Hamadryas, by E. H. J. Schuster, M.A., D.Sc.; (2) On Some Stages in the Life History of Leptomonas Muscæ Domesticæ, with Some Remarks on the Relationships of the Flagellate Parasites of Insects, by J. S. Dunkerly; and (3) On Merlia Normani, a Sponge with a Siliceous and Calcareous Skeleton, by R. Kirkpatrick. In

the first paper Schuster points out the practical importance to the surgeon of the localisation of function in the cerebral cortex, while its theoretical interest is great to the physiologist and the psychologist. The problem has been approached in different ways by the physiologist, the surgeon, and the pathologist, while the contribution called for from the anatomist and the histologist is the mapping out of the cortex into areas differing from one another in structure. The author points out that a better appreciation of a physiological and anatomical problem may be obtained by extending it into the realms of comparative pathology and anatomy, and with this end describes a special aspect of the histology of the cortex in an animal not hitherto treated in this way—viz., the papio hamadryas. The method used was Unna's polychrome variant of Nissl's methylene blue method. A detailed description of the results attained, illustrated by numerous diagrammatic plates, is given. Dunkerly has examined various kinds of house flies taken from different districts with a view to settling the nature of the flagellate parasites found in them. He reviews the previous researches of others, and concludes that Leger's original pear-shaped Crithidia is only a stage of the Leptomonas life history, and that the Crithidia of later authors—Patton and Woodcock—found in blood-sucking flies or in cultures are in some cases developmental stages of a trypanosoma. The evidence of the forms found by him in the house-fly Homalomyia canicularis shows, he contends, that Rosenbusch's Crithidia muscæ domesticæ, and therefore probably trypanosoma drosophilæ of Chatton and Alilaire, are merely forms assumed by a leptomonas.

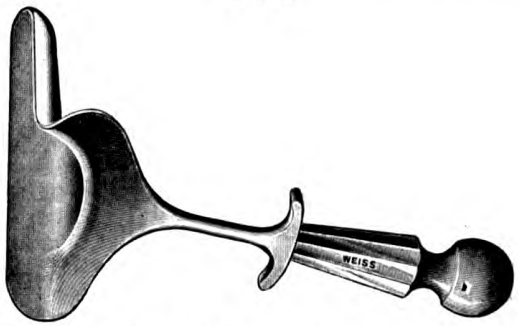
L'Hygiène.—The June number of this journal contains many interesting articles, among which may be mentioned L'Hygiène et la Vie, by M. le Dr. Maurice de Fleury; La Toxicité des Aliments, by M. le Dr. G. Linossier; La Vie Pratique et Familiale, by Madame Augusta Moll-Weiss; an interesting instalment of a series entitled "L'Art de Voyager en Italie (III.)," which deals with Palermo and is written by M. André Maurel, and the usual gastronomic articles which have become a feature of this enterprising magazine. Among the profuse and admirable illustrations we may call attention to a reproduction of a beautiful picture by Bouguereau entitled "Le Jeune Frère," depicting a young sister nursing her baby brother, both figures having this artist's inimitable grace and softness; and a powerful reproduction of the portrait of Giuliano da San Gallo, painted by Piero di Cosimo, and hanging in the Hague Gallery. *L'Hygiène* is published by Messrs. Goupil and Cie., 24, Boulevard des Capucines, in Paris, and also at 25, Bedford-street, Strand, W.C.

New Inventions.

APPARATUS FOR OPERATIONS ON THE UTERUS.

MOST practitioners have been in the position of having to operate upon a uterus per vaginam for a curettage, and have usually had to have an assistant. The following instrument has been devised to obviate this. It consists of the duckbill of a Sims's speculum, to which have been attached at right angles two flanges to press back the labia, and also to cover the anus in case of contamination (Fig. 1). This is constructed with a solid steel handle, the whole being made in one piece. The speculum will keep in its place by its own weight, the duckbill being inserted beneath the cervix uteri, thus removing the necessity of an assistant. A second instrument (Fig. 2) has also been devised for catching the cervix and holding it without tearing through, as often happens with the present type of vulsellum. It consists of two slightly curved blades broadened out to $1\frac{1}{10}$ cm. wide, the upper blade having seven teeth and the lower blade six teeth. I have now used this instrument for over two years, and never found it tear through. The last thing necessary for an operation in a private house is a proper douching sheet, and I have devised a very useful and handy arrangement

FIG. 1.



which consists of a rubber sheet, the top end of which is placed underneath the patient, the edges of the two sides being fastened together. The funnel thus formed is distended at the larger end by a piece of cane. It is easily cleaned and

FIG. 2.

extremely portable. The whole of these have been made for me by Messrs. John Weiss and Son, of 287, Oxford-street, London, W.

JEHAN M. BARLET, M.D. Brux., L.R.C.P. Lond.,
Shaftesbury-avenue, W. M.R.C.S. Eng.

A QUINSY LANCET.

THE minor operation most frequently performed by the general practitioner is, perhaps, the opening of a peritonsillar abscess, and the most common mistake is to open the abscess too high up for good drainage. I believe this is due to the use of a scalpel with too short a handle. The knife I have devised has a handle six and a half inches long, and terminates in a slightly curved and sharp-pointed blade, half an inch long, provided at its base with a broad flange. With this instrument any part of the peritonsillar region can be easily reached. The size and shape of the blade, with its flange, make it practically impossible to wound any important vessel, whilst its slight curve is sufficient to prevent its slipping before the incision is completed. In using the lancet the usual incision is made at the level of the last molar tooth, and if necessary a pair of peritonsillar forceps introduced and the wound stretched.

Messrs. C. J. Hewlett and Son, Limited, of Charlotte-street, London, E.C., have made the lancet to my design and have finished it in a most satisfactory manner.

A. CAMPBELL STARK, M.B., B.S. Lond.
Wanstead Park-avenue, E.

PRESENTATION TO A MEDICAL PRACTITIONER.—On June 29th the twenty-fifth year of Dr. D. S. Davies's tenure of the medical officership of health for Bristol was completed, and the members of his staff joined to celebrate this anniversary in a social evening, at which a silver coffee service, suitably inscribed, was presented to him. Speeches were made by Mr. J. W. Kirby, chief inspector of nuisances for the city, and Mr. S. O. Dimond, chief inspector of nuisances for the port, to which Dr. Davies replied briefly.

THE LANCET.

LONDON: SATURDAY, JULY 15, 1911.

The Royal Commission on Human and Bovine Tuberculosis.

THE final report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis, which has just been issued, is a document of great scientific interest and of extreme practical importance. It will be remembered that the Commission was appointed in 1901, shortly after KOCH'S dramatic and startling statements at the British Congress on Tuberculosis held in London during that year, to the effect that bovine and human tuberculosis were distinct from one another, and that the bovine disease was not a real source of danger to man. The members of the Commission as originally appointed were the late Sir MICHAEL FOSTER (chairman), Professor G. SIMS WOODHEAD, Dr. SIDNEY H. C. MARTIN, Sir JOHN MCFADYEAN, and the late Sir RUBERT BOYCE, with Dr. E. J. STEEGMANN as secretary. Sir W. H. POWER, K.C.B., was appointed chairman after the death of Sir MICHAEL FOSTER, which occurred directly after the completion of the second interim report, while, by a melancholy coincidence, Sir RUBERT BOYCE died during the publication of the present report, his adherence to the findings having been given. The final report is, therefore, like the interim issues, a unanimous document, which is a matter of great congratulation. The original terms of reference to the Commission were, we may remind ourselves, "to inquire and report with regard to tuberculosis: (1) whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances favourable or unfavourable to such transmission." The Commissioners have very wisely interpreted these instructions in a broad sense, and, while keeping the terms of reference always in view, have investigated many of the difficult and obscure problems in regard to human and animal tuberculosis. From time to time they have issued interim reports, to which we have alluded, and these have been summarised in our columns. The first, in 1904,[1] giving the results of the preliminary investigations, demonstrated that the bacilli found in the lesions of certain cases of human tuberculosis produced in cattle a disease indistinguishable from bovine tuberculosis. The second interim report appeared in 1907,[2] and dealt with many of the aspects of both forms of tuberculosis, and with the cultural characters and pathogenicity for various animals of bacilli of the human and bovine types. The third interim report, which was published in 1909,[3] was devoted to a consideration of certain conditions of the tuberculous cow which rendered her milk infective. To the second and third reports a number of appendices were attached, giving details of the experimental researches upon which the views expressed were based.

The final report summarises the results of the work of the Commission since its start, gives the conclusions arrived at in regard to the special references made to the Commission, and describes the special investigations carried out in connexion with tuberculosis in swine, horses, other mammals, and birds. The appendix to this report is to appear in seven volumes. Space will not permit us to do more now than refer briefly in a general notice to the main conclusions of the Commission—viz., the replies given to the three questions referred to them—but we propose in subsequent issues of THE LANCET to summarise some of the important results of the special work of the Commission, whose labours we regard as of paramount importance to the national health. In regard to the question whether tuberculosis in animals and man is one and the same, the conclusions arrived at are that the human and bovine types of bacilli are morphologically indistinguishable, but that they differ appreciably in their cultural characters and in their pathogenic effects in various animals. The difference in cultural characters is that the human type shows a greater luxuriance of growth on all the ordinary media employed than the bovine, although the bacilli belonging to this latter type vary considerably among themselves in respect of their luxuriance of growth. The pathogenic differences are, in brief, that the bovine type of bacillus produces a fatal tuberculosis in cattle, rabbits, chimpanzees, monkeys, goats, and pigs; while the human type of bacillus produces a fatal tuberculosis in guinea-pigs, chimpanzees, and monkeys, but causes only slight and non-progressive lesions in cattle, goats, and pigs. Attempts to transmute the one type into the other for the most part failed entirely, both remaining remarkably stable under experimental conditions. At the same time the possibility of transmutation under natural conditions cannot be denied, since both types of bacillus have been obtained in certain instances from a patient. Some remarkable variations from the typical pathogenicity for animals were observed in regard to some of the bacilli isolated from lupus and from equine tuberculosis, which showed the cultural characteristics of the bovine type with a virulence for the calf and rabbit no greater than that usually shown by the human type. There are reasons for discarding the possible explanation that these bacilli constitute a separate type, and they must therefore be considered as modified examples of either the bovine or human type. Such a modification of pathogenic activity obviously renders it impossible to rely upon the relative virulence for the calf and rabbit as a criterion of the non-identity of the two types. The slight cultural differences are considered by the Commission as insufficient to establish the two types as distinct organisms, and it prefers to regard them as varieties of the same bacillus and to consider that the lesions which they produce, whether in man or other animals, are manifestations of the same disease. The Commission admits, however, that there is room for difference of

[1] THE LANCET, June 4th, 1904.
[2] THE LANCET, Feb. 9th, 1907.
[3] THE LANCET, Feb. 13th, 1909.

opinion in regard to the point, but it is insistent in emphasising the fact that in a considerable proportion of cases of tuberculous disease in man the lesions are caused by bacilli in every respect indistinguishable from the bovine type. The reply to the second term of the reference to the Commission—viz., whether animals and man can be reciprocally infected with tuberculosis—is very definitely and unequivocally in the affirmative. Bovine animals are not completely immune to the human type of bacillus, although they possess a high degree of resistance to it. On the other hand, as has just been mentioned in connexion with the first reference, the bovine bacillus has been found in cases of tuberculosis in man, even the pulmonary form of the disease being sometimes caused by this type of organism. It is of interest to notice that the majority of human cases from which bovine bacilli were recovered were instances of tuberculous disease in childhood. The third term of the reference—viz., to determine under what conditions, if at all, the transmission of tuberculosis from animals to man takes place, and what circumstances are favourable or unfavourable to such transmission—is a very wide one, and although the subject has been studied with great care by the Commission they have obviously been able to investigate only certain aspects of it. They find that, whatever may be the animal source of tuberculosis in adolescents and in adult man, there can be no doubt that a considerable proportion of tuberculosis affecting children is of bovine origin, more particularly those forms involving primarily the abdominal organs and the cervical glands, and further they maintain that there can be no doubt that both of these conditions are commonly due to ingestion of tuberculous infective material. Even in adolescents and adults so large a proportion of the cases investigated, i.e., 5 out of 55, showed the presence of bacilli of the bovine type as to indicate the same sources of infection as are possible at other periods of life than childhood. The importance consequently of strict administrative measures to deal with the prevention of the danger from infected milk and meat is urged by the Commission, whose attitude serves to illustrate the important practical bearings of the work.

We have nothing but admiration for the manner in which the Commission has discharged its duties. The interim reports and their appendices have already attained an important authoritative position in the literature of the subject, and the final report will be of immense value, both because of its clear and unanimous conclusions, and of the mass of original work on which they are based. The one source of regret in connexion with this final report is that the Commission is not to be organised into a permanent bureau. It must be obvious to all that the pathological and public health problems connected with tuberculosis are by no means settled as a whole; there yet remain many aspects even of the actual matters investigated by the Commission upon which further work, extending over a series of years, is desirable. At the present time, when public and Parliamentary interest is actively aroused in connexion with the treatment of tuberculous disease, and when it is proposed to devote large sums of money to this object, it seems to us peculiarly inopportune to dissolve this Commission, with its highly trained workers, its accumulated store of material, and its intimate grasp of the problems involved. Other Tuberculosis Commissions have been appointed and dissolved, with the result that each fresh one has to start again, not where the previous one left off, but with a great deal of needless preliminary work to perform. We feel confident that if the present Commission is dissolved another will ultimately have to be appointed, and we would urge upon those with whom the decision lies that to devote a sum to maintain the mechanism of the present Commission would in the long run be an economy, for it would certainly yield further important scientific and practical information out of all proportion in mere money value to the outlay involved.

Sun-stroke.

THE unusually prolonged heat-wave of great intensity that has recently afflicted North America, and which is at present threatening us, renders it not amiss to consider briefly the various theories advanced in explanation of the deleterious action of the sun's rays on man as well as the methods of their prevention. The sun may excite the forms of injurious effect known respectively as heat-collapse and heat-stroke. Heat-collapse is not usually a severe condition. The patient suddenly turns giddy and falls; his skin is moist and cool; his breathing hurried but never stertorous; his pulse small and soft; his pupils dilated; his temperature remains at, or falls below, the normal; whilst there is no complete loss of consciousness as a rule. Recovery generally ensues when the patient is taken into the shade, his clothes are loosened, cold water is dashed on his head, and ammonia held to his nostrils. Far different, however, is it with heat-stroke. This may be either direct or indirect. In *direct* heat-stroke, or sun-stroke, the attack may occur in more than one form. In one form the persons affected are mostly more or less untrained to severe exertion, as, for instance, young soldiers newly arrived in a hot country and unaccustomed to the fatigues of marching, and it is especially likely to affect them when the air is moist, so that the skin action becomes diminished. Violent headache is first complained of; the march, however, is still continued, until the patient at length falls down in convulsions, with teeth firmly clenched, insensibility absolute, dyspnœa, small and weak pulse, and often incontinence of urine. In a second form the subject, streaming with sweat, becomes progressively paler, with cyanosed lips, injected eyes, swollen veins, respiration shallow and quiet, until he slips to the ground. Consciousness is not, as a rule, entirely lost, and revival occurs if the patient be relieved of all impediments to free respiration. In yet a third form the subject becomes extremely thirsty, without any feeling of fatigue, and suddenly falls down comatose. The state of coma may last from 24 to 36 hours and may end in death without any recovery of consciousness. Lastly, in a fourth variety, the soldier, after a hot and wearying march in the sun, is seized with a racking headache, which hourly becomes more and more intense, so that within 24 hours he may be rolling about in agony from the terrific pain in the head. Soon great intolerance of light sets in and then unconsciousness.

Should the patient not die, the intense pain in the head on return to consciousness may last for six or eight weeks unrelieved by any drug, though showing slight evening remissions. It then gradually abates. In the indirect form of heat-stroke the individual is attacked indoors. He becomes pale and nauseated; has colic and incontinence of urine. Convulsions follow, to be succeeded by cyanosis, dyspnœa, and insensibility, with stertor and contracted pupils. The temperature may run up to 110° F., remaining high for some time after death.

Such are briefly the various ways in which an individual may be attacked by the sun. To consider next the various theories advanced of the causation of heat-stroke, we have first the *caloric* theory, which attributes the attack to the action of intense heat *per se*. It is supposed that the intensity of the heat disturbs the regular action of the heat-regulating centres of the body. To this, however, it must be objected that stokers of the steamships in the Red Sea are scarcely ever affected by the heat of the furnaces. Next, there is the *autotoxic* theory, according to which the high temperature causes the blood to become poisonous to the nerve cells, especially those of the vasomotor centres and cardiac ganglia. Then we have the microbic theory of Dr. L. SAMBON. This theory can hardly be sustained, at any rate so far as India is concerned, according to most observers in that country. Dr. SAMBON states that as regards geographical distribution, the endemic area is limited to the lowest region, coast districts, and valleys of great rivers. Now Colonel J. A. CUNNINGHAM, I.M.S., has shown that the very lowest rates for heat-stroke are given by the Burma Coast, the Bay Islands, and the West Coast of India, the lowest regions of the 12 geographical districts into which India is divided for statistical purposes. Again, the author of the theory asserts that, with regard to the meteorological conditions, the disease does not especially coincide with the hottest days. The statistical tables of India, however, show that the greatest mortality from heat-stroke exists in the Punjab, Scinde, and on the North-West Frontier—the hottest parts of India. Lastly, this supposed microbe has not yet been seen. True, CAGICOL and LAPIÈRE have described one, but their observations lack confirmation. STILES, of Edinburgh, by injection experiments, seems to have excluded the presence of any toxin.

The view that, in our opinion, best accounts for heat-stroke is the actinic theory of Colonel F. MAUDE, R.E. This distinguished officer had suffered from several attacks of sun-stroke, when he conceived the idea that the rays of the sun which caused such attacks were not the heat rays, but the actinic rays situated at the other end of the spectrum. It occurred to him that if he lined his helmet with red to cut off these chemical or actinic rays (just as the photographer lines his dark-room with red for the same reason in developing), he would obviate the disastrous effects of the sun. He tried it, with the result that for many years he experienced no further ill-effects from the sun. An officer who did not believe in the theory, however, one day surreptitiously abstracted the red lining from Colonel MAUDE'S hat as he was about to expose himself to the sun, with the result that Colonel MAUDE again suffered from sun-stroke, and experienced great chagrin at the supposed failure of his theory until the repentant officer told him what he had done. Another officer, who had previously suffered on three occasions from sun-stroke, causing him to be invalided for nearly five years, also lined his helmet with red, with the result that as each succeeding hot weather season came round he was enabled to live without any discomfort from the sun, although he had previously suffered severely from headaches. The plan of lining the head coverings with red or orange flannel, therefore, certainly seems to deserve a more extended trial. As regards diet, moderation must be practised both with meat and drink. The late Surgeon-General W. C. MACLEAN, unquestionably an authority on tropical diseases, used to warn his class at Netley against the eating of meat more than once a day in the tropics. Alcoholic drinks should never be taken by those exposed to a hot sun. The best beverages are tea and coffee, the good effect of which will be easily understood when we remember that the sun's action diminishes the activity of the skin and lessens that of the nervous system, diminishing the excretion of carbonic dioxide and inducing cardiac paralysis, whereas tea and coffee have precisely the opposite effects.

The Discovery of the Functions of the Spinal Roots.

QUESTIONS concerning priority of scientific discovery are often best left to pass swiftly to the practical oblivion of the work-a-day world's neglect. But there stand exceptions: where the forward step achieved was epoch-marking, where the competing names are great, and where the rival claims involve the chivalry of sister nations. The discovery that the anterior and posterior roots of the spinal nerves are respectively motor and sensory in function stands in this position. It forms an event of capital magnitude in the history of medicine and biology. It can be assessed as a true compeer of the discovery of the circulation of the blood. It inaugurated and led on to the whole modern understanding of the nervous system so far as localisation of function is concerned. HARVEY'S discovery was more dramatically placed, since as regards biology it formed the *point du jour* of the whole Renaissance. With it the seventeenth century of Western Europe in one act lifted and relit the torch fallen from Greek hands 12 centuries before. So likewise with the discovery of the functions of the nerve-roots neurology passed at one stride from the world of GALEN to the modern era. It is odious that the true authorship of such an advance should lie in doubt, although the event itself is not yet a hundred years gone by. To attach to a discovered fact the name of its discoverer is an excusable grace whereby the aftercomers, late aftercomers who reap what they did not sow, mark their gratitude and perpetuate it. The name which we in this country commonly attach to the discovery of the root-functions is that of CHARLES BELL. But the claim is disputed. The doubts that have from time to time, even from the date of

BELL'S reclamation of the discovery, found voice have recently been clearly and dispassionately set forth in some correspondence in our columns. To give the discovery to BELL is to deprive of it another claimant—namely, the French physiologist, MAGENDIE. To do so unrightly would be the more regrettable in view of the French *savant's* dignified magnanimity throughout. BELL'S reclamation left unconvinced some who were, and still leaves unconvinced some who are, well qualified to judge it.

BELL, prior to the work of MAGENDIE, had on inferences from the naked-eye anatomy of the mammalian brain argued that the cerebrum through the pyramid was continuous with the anterior spinal column and the anterior roots; and that the cerebellum through the restiform body was similarly continuous with the posterior column and the posterior roots. By these two roots respectively, he argued, cerebral and cerebellar influences were separately dispensed and distributed to the peripheral parts. In an animal freshly killed he had found the anterior root respond to rough mechanical irritation, while the posterior root remained silent. This he regarded as confirmatory of his view, for the cerebellar function he thought to control the "secret actions of the bodily frame," and "especially govern the operations of the viscera." These naive speculations with their halting experimental basis resemble little the boldly decisive observations made by MAGENDIE, acknowledged master as he was of the physiological technique of his time. MAGENDIE showed that in the dog severance of the anterior roots leaves the limb fully sensitive but wholly paralysed as to motion, and that conversely severance of the posterior roots leaves the limb wholly insensitive but not paralysed as to motion. His demonstration left this result fixed beyond possibility of cavil. But of the posterior root BELL'S expression had been that it was "insensible." The anterior root he had considered "sensible" as well as motor. It is therefore not mysterious why, despite BELL'S publications, the true doctrine of the functions of the spinal roots remained unpromulgated until MAGENDIE'S announcement of it in 1822. The true doctrine had not been promulgated for the simple reason that it had not been arrived at. The "Idea of the New Anatomy of the Brain," published by BELL 11 years before, in 1811, did not contain it. That it did not anyone who, in the libraries of the British Museum or Royal Society, will turn to it may see. The rival claims as they emerge once more from the discussion in our columns seem therefore to admit of clear decision. It were, however, well if all the circumstances could be entered into and pronounced on once for all by some competent tribunal with a *personnel* such as should lend to its judgment authority and practical finality. We should ourselves be prepared to accept Dr. A. D. WALLER'S verdict, as delivered in THE LANCET of June 24th, p. 1718, but as this has already been appealed against in our columns he would probably consider that some further tribunal is called for. The question is for us in this country to some extent an affair of honour. If justice has yet to be satisfied it is high time the duty should be discharged with full publicity and without longer delay.

Annotations.

"Ne quid nimis."

THE BABEL OF HOOTERS.

WE were accused of making a puerile proposal when we held it to be desirable rather more than a year ago that in the matter of methods of warning in our thoroughfares some uniform system should be adopted by motor vehicles. "As things stand," we wrote previously, "there is nothing apparently to prevent the most fantastic methods of alarm being adopted, and the result may be irritating, if not occasionally disastrous, to the public. ..... In some instances the alarms are unnecessarily exaggerated and weird, and when a more or less foreign noise is released the effect may well give a shock to nervous persons." Several leading members of our profession have recently endorsed this view in the public press, and the layman is beginning to realise that a new and real infliction is rapidly being forced upon him. London is intolerable, not only by day, but by night also, on account of its Babel of motor warning sounds. As we previously urged, there should be a standard warning, and this warning should not be unnecessarily sounded. As it is, there are hundreds of horns on the motor vehicles in London which send forth an irritating blare, the note of which may be included anywhere in a range of a couple of octaves. On one vehicle there is the top note like a cornet, on another there is the middle note like a clarinet, and on a third there is the low note like a bassoon, and so on. Then there is the fiendish device by which the exhaust actuates a screaming syren or succession of notes or even an attempt to produce a chord. This confusion and multiplicity of sounds to gain a common and a humane end is completely illogical, and irritating beyond measure. We protest against this outrage upon the human endurance, thrust upon it not only by day but in what should be the resting hours of the night. There can be no question of the reality of the evil, and our authorities must be pressed to eradicate it from our midst. There is distinct medical testimony as to its possible effects, and the evil could be materially reduced, it seems to us, by enforcing a standard method of warning and preventing the superfluous use of the "hooter."

TUBERCULOSIS AND THE NATIONAL INSURANCE BILL.

THE National Association for the Prevention of Consumption has decided to devote the whole of its forthcoming annual meeting, to be held at the Caxton Hall, Westminster, on July 19th, 20th, and 21st, to a consideration of the best ways of employing the grants to be voted in the Budget for dealing with tuberculosis. An exceptionally strong executive committee has the work of organisation in hand, and many of its members will also take an active part in the proceedings. The proceedings will be divided as follows into five sections:—July 19th (morning): I. *Education:* Introductory address by Professor G. Sims Woodhead; (*a*) The School in the Campaign against Tuberculosis, by Dr. F. C. Shrubsall; (*b*) Tuberculosis Exhibitions and Caravans, by Sir William Younger, Bart.; (*c*) The District Nurse and the Health Visitor, by Mrs. Howard Marsh; (*d*) Propaganda among the Friendly Societies and Trade and other Organisations of the Working Classes, by Mr. J. Lister Stead, secretary, Ancient Order of Foresters. Afternoon: II. *The Machinery of Detection:* Introductory address by Dr. R. W. Philip; (*a*) The Hospital Outpatient Department, by Dr. R. C. B. Wall; (*b*) The Tuberculosis Dispensary, by Dr. H. G. Sutherland; (*c*) Other

Methods and Organisations: (1) Public—by Dr. James Niven, Dr. J. M. Ross, and Miss Bibby, sanitary inspector, Borough of St. Pancras; (2) Voluntary—by Miss Cowen, honorary secretary of the Health Committee, Jewish Board of Guardians. July 20th: III. *Treatment:* Introductory Address by Sir William Osler, Bart.; (*a*) Sanatorium Treatment, by Dr. A. C. Latham and Dr. Jane Walker; (*b*) The Educational Value of the Sanatorium, by Dr. M. S. Paterson and Dr. J. J. Perkins; (*c*) Home Treatment, by Dr. J. E. Squire, C.B., and Home Treatment of Persons under 16, by Dr. J. F. J. Sykes; (*d*) Open-air Recovery Schools, by Dr. Ralph P. Williams; (*e*) Tuberculosis Schools, by Miss McGaw, Member of Council, N.A.P.C.; (*f*) Advanced Cases and Segregation, by Dr. A. Maxwell Williamson. July 21st (morning): IV. *After-care of Patients*, by Mr. C. S. Loch, secretary of the Charity Organisation Society, and Dr. H. W. McConnel, to be followed by a general discussion. Afternoon: V. *The Administrative and Financial Aspects of the Bill.* Introductory Address, by Dr. W. Leslie Mackenzie: (*a*) The Cost to the Community, by Mr. Waldorf Astor, M.P.; (*b*) The Use of Existing Accommodation, by Dr. Nathan Raw; (*c*) The General and Medical Aspects of the Insurance Bill, by Mr. Ernest J. Schuster, LL.D. The Tuberculosis Exhibition of the association will be on view. In view of the importance of the occasion the meeting is likely to prove of exceptional interest, as is shown by the ready response of all the public bodies having control over tuberculosis in the three kingdoms to a request that they should be represented by delegates, and by the prominence of all the contributors. It is expected, moreover, that Mr. John Burns and possibly the Chancellor of the Exchequer will attend.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE annual meeting of the British Medical Association at Birmingham is now almost in sight, and all arrangements are practically complete. The annual meeting itself commences on Tuesday, July 25th, and continues during the next three days, but the annual representative meeting begins on Friday next, July 21st. Professor Robert Saundby, physician to the Birmingham General Hospital and professor of medicine in the University, is the President-elect of the Association, and Sir Henry Butlin, the retiring President, will vacate the chair for him on Tuesday, July 25th, at 2 P.M. Professor Saundby will deliver the Presidential Address at 8.30 P.M. that evening in the University, Bournbrook, Birmingham. On Wednesday, July 26th, at 12.30 P.M., Dr. Byrom Bramwell will deliver an Address on Medicine. On Thursday, at the same time, the Address on Surgery will be delivered by Professor Jordan Lloyd. Sixteen scientific sections have been arranged and will meet daily from Wednesday to Friday in the University Buildings at 10 A.M., viz.:—Anatomy and Physiology; Dermatology; Diseases of Children; Electro-Therapeutics and Radiology; Laryngology, Otology and Rhinology; Medical Sociology, including Medical Inspection of School Children, Hospital Administration and Contract Practice; Medicine; Neurology and Psychological Medicine; Obstetrics and Gynæcology; Odontology; Ophthalmology; Pathology; State Medicine and Industrial Diseases; Surgery; Therapeutics, including Dietetics; and Tropical Medicine. Throughout the meeting an Exhibition of Surgical Instruments, Drugs, and Foods will be open daily in the Bingley Hall. The annual dinner will be held on Thursday, July 27th, at 7.30 P.M., at the Grand Hotel. Religious services have been arranged for the opening day, followed by garden parties and a reception. Various other social arrangements have been made for members and ladies accompanying them, and on Saturday there will be excursions. Matters of great moment in connexion with the Insurance Bill will be considered by the representatives, and also referred to in the Medico-Sociological Section.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: NEW ADDITIONS TO THE MUSEUM.

IN THE LANCET of July 1st (p. 30) we announced that the annual exhibition of specimens which have been added to the Museum of the Royal College of Surgeons of England during the past collegiate year would be on view at the College on July 6th, 7th, and 8th. The following is an analysis of the specimens acquired: Pathological series, 193; surgical instruments, 4; teratological series, 34; human anatomy series, 8; physiological series, 101; histological series, 720; osteological series, man 85, vertebrata 16; odontological series, 27; and miscellaneous series, 15; making a grand total of 1203 specimens. Among the several donations it may be noted that H.M. the King presented another pheasant illustrating alteration in the secondary sexual characters of the hen bird. The President presented 43 drawings of cases of cancer and conditions which may be mistaken for cancer of the tongue. Many of these are in water colours and have been prepared by a skilled artist. Professor F. D. Bird of Melbourne gave 32 stereoscopic radiographs illustrating anatomical and surgical aspects of the human body. The collection of microscopical preparations, made by the late Mr. Cresswell Baber during his research on the comparative anatomy of the thyroid, and on which he based his paper in the Philosophical Transactions, 1881, was presented to the College by Mrs. Cresswell Baber. This valuable addition, amounting to 712 preparations, will be placed in the histology collection. Further additions to the pathology of tropical diseases have been received from Captain A. Whitmore, I.M.S., Rangoon, and from Dr. R. D. Keith, Dr. G. A. Finlayson, and Dr. S. M. Livesey of Singapore. Numerous donations have been made to the ethnological series. Through Dr. C. G. Seligmann 26 crania were obtained from various parts of New Guinea, and Mr. R. R. Williamson also obtained for the Museum crania from a newly discovered New Guinean tribe. Mr. P. A. Talbot presented five crania of natives of Southern Nigeria, a region at present imperfectly known from an ethnological point of view. Professor A. Watson of Adelaide University has presented various specimens which illustrate the anatomical peculiarities of the natives of Australia. The Egypt Exploration Fund and Professor G. Elliot Smith have presented further specimens which help to fill out the data relating to the physical structure of the ancient Egyptians. Additions to the Maori and Mallicollo crania have been made by Mr. E. W. Merton Holmes of Sutton, Surrey, and Mr. S. W. MacIlwaine of Clevedon. Many additions have also been made to the prehistoric British series. Mr. W. M. Newton presented a cranium found by him in the 60-foot gravel terrace of the Thames Valley at Dartford; this presumably is one of the oldest skulls found in England. Through Mr. F. G. Parsons a collection of bones excavated from an ancient cemetery near Folkestone, and assigned to the Jutes, was added to the Museum. Other valuable additions have been made to the prehistoric series by the Rev. J. W. Hays, Mr. W. Storrs Fox, Dr. Arthur R. Waddell, Mr. F. J. Bennet, Dr. J. Arnalt Jones, Mr. Frank Corner, Dr. Eric Gardner, and Colonel Willoughby Verner. As announced in the last annual report, a large and extensive collection of specimens, illustrating the experimental production of tuberculosis, has been presented by the Royal Commission on Tuberculosis. The description, cataloguing, and arrangement of this collection will take some considerable time, but it is hoped that in the course of the present year these specimens will be available for study by visitors to the Museum. Another gift of importance is

that made by the Imperial Cancer Research Fund, which has handed over to the College a complete series of specimens illustrating the artificial cultivation and propagation of cancer in mice. These specimens have been mounted and are at present on exhibition at Munich. Through Mr. Hammond Smith of the *Field* the Museum has received many illustrations of rare and instructive pathological lesions and developmental anomalies in game. Important donations have also been made by Colonel C. E. Shepherd, Mr. J. Bland-Sutton, the Australian Museum of Sydney, the Imperial College of Science, British Museum (Natural History), Mr. H. Balean, Dr. W. Blair Bell, Dr. F. Wood Jones, Mr. C. B. Lockwood, Mr. N. Hill, Professor T. Wardrop Griffith, Dr. A. Morison, Mr. H. Rischbieth, Professor A. L. Sheather, Professor Gustav Retzius, Dr. Ivy Mackenzie, Mr. A. R. Tweedie, Dr. H. A. Lediard, Dr. Leonard Guthrie, Mr. James Sherren, Mr. A. Hopewell-Smith, Mr. C. P. Childe, Mr. P. I. Watkin, Mr. S. Smulian, Mr. J. D. Malcolm, and Dr. J. F. McCann. Several important additions have been made by purchase. Amongst the most remarkable of these is a series of nine complete skeletons of Bushmen, a dwarf race rapidly becoming extinct, and of whom, says Dr. Arthur Keith, the Conservator, in his report, our knowledge is imperfect. In one individual the teeth of the upper jaw have ground against the lower jaw so as completely to expose the canal for the inferior dental nerve. This series of skeletons provides, for the first time in this country, an opportunity of making a complete study of the osteology of a dwarf race. Mr. W. M. Borcherds, a Member of the College, of Uppington, Cape Colony, made it possible for the College to acquire these specimens. An opportunity also occurred during the year of giving a very full representation of the pathological changes which occur in acromegaly.[1] So far as Dr. Keith has been able to discover, the skeleton of the subject of the disease—a male—is the only complete specimen in England.

ACUTE GANGRENE OF THE COLON.

IN the *Edinburgh Medical Journal* for May Mr. J. W. Dowden has reported a remarkable case of a very rare lesion —acute gangrene of the cæcum and of the whole colon. A labourer, aged 51 years, who was working on a night shift, was admitted into the Edinburgh Royal Infirmary at 10.30 P.M. on Jan. 13th, 1908. On that morning he returned from work, went for a walk, and took a meal before going to bed. At 11 A.M. he was seized with pain in the lower abdomen which soon began to swell visibly. The pain quickly became general over the abdomen, and he vomited some ill-smelling fluid. He passed neither fæces nor flatus after the onset of symptoms. He stated that just before admission he passed pure blood by the urethra. He had always been healthy until three weeks before admission, when he began to suffer from griping pains in the morning and some diarrhœa, chiefly mucus. At times he suffered from constipation. On admission he looked young for his years, and healthy except for some lividity of the face, which betokened anxiety and pain. There was evident dyspnœa, the respirations being 36. The temperature was 97° F., and the pulse 136, small, and compressible. The abdomen was much distended and did not move on respiration. On palpation there was remarkable absence of pain. The percussion note was tympanitic. Examination of the hernial regions and rectum revealed nothing. The urgent nature of the symptoms pointed to acute obstruction, which was thought might be due to volvulus. On the other hand, the history of "diarrhœa" with mucus at his age suggested malignant disease low in the large intestine. At 11 P.M. an incision was made to the left of the middle line chiefly in the lower half of the abdomen, and the anterior sheath of the rectus was split in its long axis. So great was the intra-abdominal tension that the fibres of the rectus separated, but no hernial protrusion occurred. The posterior sheath of the rectus was so tense and stretched that it was impossible to pick it up with forceps, and it therefore was opened by careful incision. It was surprising that nothing protruded from the peritoneal cavity. The coils of small intestine were somewhat congested but not distended. The incision was enlarged upwards and the cause of the distension appeared in the shape of a purple-black transverse colon distended to the size of a coat sleeve. The peritoneal coat was ruptured in its long axis. The colon was punctured with a trocar and cannula, but only gas, not under pressure, escaped, and the bowel did not collapse at all. The cæcum, ascending, transverse, and descending colon were similarly affected. The abrupt termination of the process at the ileo-cæcal junction and at the end of the descending colon was striking. At the latter point was a malignant tumour. No occlusion of arteries could be discovered. The patient's condition was such that nothing more could be done than tie a Paul's tube into the transverse colon. He was relieved by the operation, but rapidly became worse and died at 11 A.M. At the necropsy the abdomen was extremely distended and contained 15 ounces of turbid fluid. The large intestine was distended, dark, and gangrenous from the cæcum to the termination of the descending colon. Throughout this extent its serous coat was ruptured. The mucous coat was of a pale salmon-pink colour and healthy except for occasional petechiæ and minute follicular ulcers. There was a breaking-down annular carcinoma of the sigmoid flexure. The kidneys showed advanced fatty degeneration with chronic interstitial nephritis. The spleen was soft and diffluent. Cultures made from the intestine and spleen gave a mixed growth of the colon bacillus and Gram-positive diplococci. The spread of gangrene from the appendix to the cæcum is well-known, but of such extensive gangrene of the large intestine as was here present only two cases appear to have been recorded—by an American writer, Lanphear. In one, a boy, aged 7 years, was operated on for appendicitis with a huge abscess. Eight months later he was operated on again 38 hours after the onset of abdominal pain. There was gangrene of the entire colon and a band of adhesions located at the cæcum encircled the lower portion of the descending as well as the ascending colon. In the second case there was thrombosis of every artery of the meso-colon, of which the cause was unknown.

EMOLUMENTS IN THE INDIAN MEDICAL SERVICE.

WE continue to receive letters from correspondents in India giving expression to the feelings of dissatisfaction that are, unfortunately, widely prevalent in the Indian Medical Service. In a communication printed in our issue of July 8th (p. 124) our informant draws attention to the fact that in India an officer of the Royal Engineers draws more pay than an Indian Medical Service officer of corresponding rank. We are not always in love with comparisons, bearing in mind Dogberry's philosophical dictum, but in this case there appears to be distinctly a grievance, when an officer, who has provided himself with an expensive professional education before entering the service, receives less pay than another officer of corresponding rank who has had his professional training provided for him at the expense of the State. With regard, however, to the comparison of Royal Engineer and Indian Medical Service officers in civil employ, we consider that an Indian Medical Service officer when given a civil charge is placed in a position where

private practice is, as a general rule, obtainable. This is certainly not the case everywhere, but we believe it is still the case, as a rule. If it were not so there would hardly be the general desire to enter this branch that we believe still exists. There is little doubt, however, that this attraction to civil employ is less than it used to be, and the official policy appears designed to diminish it still further. The complaints as to difficulty in getting leave and the excessive number of transfers amongst junior officers are well founded. Formerly this might have been due to inefficient administration. At present we have no doubt that the higher authorities have great difficulty in carrying on the administration at all, owing to the scarcity of officers. As we have previously stated on several occasions there is urgent need for the Indian Government to deal without delay with the conditions causing dissatisfaction in the medical service; the discontent is increasing, and in many respects is well founded. We still think, however, that there is some exaggeration in the statement that the cost of living has been doubled, and the purchasing power of the rupee halved, in recent years; we should be glad to be informed of specific instances. There is great variation between different parts of the country and between different stations, some of which are notoriously expensive. We are viewing the question from the standpoint of the Indian Service as a whole.

THE ETIOLOGY OF TYPHUS FEVER.

SEVERAL reports have been lately published which have extended our knowledge of typhus fever. After failing to infect monkeys and small quadrupeds by injections of blood from human typhus cases, Nicolle[1] found that the chimpanzee would react and that the infection could be passed on to another ape. Then E. F. McCampbell of Columbus University, Ohio,[2] discovered that a fever could be excited in apes by the injection of the blood of a patient suffering from "tabardillo," which is typhus fever as it occurs endemically in the upper tableland of Mexico, and that the virus, uncultivable and invisible even with dark-ground illumination, did not pass through a Chamberland filter. At the same time Anderson and Goldberger, of the Public Health and Marine Hospital Service, came to the same conclusions,[3] and showed further that one attack of this fever produced by inoculation protected against a second infection; also that the virus would not pass a Berkefeld filter. Lastly, Dreyer,[4] working amongst typhus cases in Egypt, without knowledge of these other investigations, has confirmed them with singular completeness, and has shown in addition that an ape which failed to react to filtered serum was yet not insusceptible, for when unfiltered blood was subsequently injected into it the usual fever developed. Our present knowledge drawn from these researches then amounts to this, that the exciting cause of typhus fever cannot at present be made visible either in fresh blood or in stained films of the blood or smears from organs, and that it is not a filter-passer. Dreyer suggests that it may be invisible because lodged within a cell; this would also prevent it from passing filters. None of the observers named have been able to get a growth from the blood on any medium. Inoculation of the blood of a typhus patient into certain apes is followed, after an incubation of from 8 to 18 days, by a fever of sudden onset, lasting a week, with hebetude and anorexia as its characteristic symptoms, and ending generally by crisis; a milder fever than typhus in the human subject, but yet presenting a quite characteristic and recognisable clinical picture. Blood taken from the animal during the pyrexia and inoculated into another ape will excite a similar condition, and one attack confers an immunity. Rabbits and guinea-pigs are not susceptible, but they do react to blood from cases of Rocky Mountain spotted fever, and this is partly why that fever has come to be thought different from typhus fever. But the most important question for us is how the disease spreads, and the epidemiology of the infection is supposed to point to an insect as the carrier, attention being directed to the louse, the bug, and the flea. Typhus fever, to be infectious, requires very close contact. It does not spread in a clean house, nor in a hospital, except to those of the staff who handle the clothing of the newly received patients (Nicolle). In Tunis, in one epidemic centre there were no bugs, in another no fleas, while in the mines that were infested with fleas the Europeans who had no lice escaped typhus fever altogether. Anderson and Goldberger decide that if the infection were carried by the flea, the disease would be infectious at greater range, and that it would not exclusively attack the poorer classes. Then they think that as it is a disease less attached to houses than to persons, and as it particularly attacks armies in the field (who have no beds), it cannot be carried by bugs. As, however, armies are specially apt to be infected with lice, suspicion falls on pediculus vestimentorum, and that would explain the marked incidence of typhus fever on people brought intimately into relation with the sick: medical men, nurses, clergymen, and laundresses. These writers have made some experiments confirming Nicolle's observations that lice were apt to die at temperatures over 70° F., and thus they explain the prevalence of tabardillo on the cool Mexican plateau (where the lice would be active and hungry), and its absence from the hotter zone down by the coast. Like Nicolle, they think that they have succeeded in conveying infection to an ape by the bite of infected lice. The Rocky Mountain spotted fever we have mentioned is also supposed to have an insect carrier, a wood-tick, for here the disease and the insect have a similar seasonal prevalence.

THE MEDICAL INSURANCE COMMITTEE.

A MEETING of the Medical Insurance Committee was held on Tuesday, July 4th, at the offices of the British Medical Association, when the annual report of the committee was read and adopted. The full committee at the present time consists of Dr. G. E. Haslip (chairman), Mr. L. E. Creasy, Mr. Guy Elliston, Sir Frederic Hewitt, M.V.O., Mr. Hugh R. Ker, Dr. J. A. Macdonald, Dr. Donald J. Mackintosh, M.V.O., Dr. S. Squire Sprigge, Mr. J. Smith Whitaker, and Dr. Dawson Williams. As the work of the committee has been regularly noticed in our columns it may seem unnecessary to describe its scope to our readers, but the movement, though becoming so successful, is still a very young one, and deserves all legitimate prominence. The committee had its origin in a correspondence in THE LANCET (?), the importance of which was recognised by certain influential members of the British Medical Association, and has now been carrying on its business close upon four years. The committee was started to secure for medical men the best terms possible for all classes of insurance, and after paying working expenses to distribute any surplus to deserving medical charities. It has fulfilled its objects in a thoroughly satisfactory manner. To quote from the chairman's report, which was adopted at this meeting: "That the main object has been achieved is demonstrated when it is borne in mind that up to the present the committee has returned to medical men insuring through the agency, in the form of rebates, a sum exceeding £1500, and has handed over to medical charities some £140." The

following figures of the annual turnover of the Medical Insurance Committee from the starting of the agency are also to be found in the chairman's report, and demonstrate that the advantages of the work done by the committee are being appreciated as its operations become more widely known :—

1907	1908	1909	1910
£1358	£1725	£2463	£4867

In turning to the figures for the year ending Dec. 31st, 1910, it is satisfactory to record progress all round. Employers' Liability and Personal Accident shows an increase in premium income of £94 ; Life, £245 ; Fire, £20 ; Burglary, £14 ; Motor Car, £1886 ; and Sundry Insurances, £91 ; giving a total increase of £2350 in premium income. As regards Motor Car Insurance over £2000 was taken in premiums. The "Red Cross" Doctor's Policies have been much utilised, as is proved by the large increase of business. In these circumstances we have no hesitation in commending the work of the committee to the close attention of our readers. They can do good to others and obtain substantial permanent benefit for themselves under it operations.

A SAFE AND EFFICIENT ANTIRABIC VACCINE.

EVERYONE will agree with Sir David Semple when he lays down that the two cardinal factors to be considered in the preparation and administration of vaccines, whether preventive or curative, are safety and efficiency. These were the two points on which Pasteur originally concentrated his attention, and the principles that he laid down have been universally adopted wherever antirabic treatment has been carried out. With regard to bacterial poisons, it has been established that the "vaccines" obtainable from the dead bacteria produce immunity; in small-pox itself the attenuated living vaccine of the modified disease, vaccinias is used as a prophylactic ; for inoculation against typhoid and cholera dead cultures of the specific bacteria are used ; for rabies Pasteur commenced treatment with a dead virus, and having procured a certain degree of immunity followed it up by injection of the living virus. Högyes of Budapest introduced an antirabic treatment by injecting high dilutions of a living virus to begin with, following on with lower dilutions carefully graduated; this is known as the "dilution method," it being supposed that a rabies toxin does not exist separated from the living virus. In the "dried cord" method of Pasteur the existence of a toxin is assumed in the nerve centres (brain and cord), the principal seat of the virus, and the focus of its multiplication. In a recent research [1] Sir D. Semple has endeavoured to ascertain whether animals can be as highly immunised against rabies with a dead as with a living virus ; for if this be the case, it would follow that such a vaccine would be both safe and efficient, and would possess the two most essential properties of an antirabic or any other vaccine. To procure a dead antirabic vaccine heat may be used, followed by the addition of antiseptic to preserve the vaccine and to guard against subsequent contamination ; or an antiseptic only may be employed. It was found that rabies virus was easily destroyed by heat ; a temperature of 50° C. kills a 5 per cent. dilution of "fixed virus" in 15 minutes. With regard to carbolic acid, it is to be remembered that an efficient rabies vaccine should contain at least 2 per cent. rabies virus, and not more than 0·5 per cent. carbolic acid, when administered to the patient; now such a vaccine cannot be obtained simply by killing the virus with carbolic acid at ordinary room temperature, for the amount of carbolic acid required would be too large to be capable of subsequent dilution without at the same time over-diluting the vaccine. After numerous experiments it was found that with an 8 per cent. dilution of rabies virus in normal saline the virus was killed by 1 per cent. carbolic acid at 37° C. in 24 hours ; this fluid being then diluted with an equal volume of normal saline becomes a "4 per cent. rabies virus in 0·5 per cent. carbolic acid normal saline solution" ; this is a very suitable strength of virus for antirabic treatment, and contains sufficient carbolic acid to prevent any chance of subsequent contamination when stored for use after being made up. The next point was to determine the efficiency of this vaccine against lethal doses of living rabies virus. Four monkeys, two dogs, and two rabbits were subjected to treatment, the vaccine being injected hypodermically on the sides of the abdomen, one dose daily ; all the monkeys, one dog, and one rabbit survived the subsequent subdural inoculation of lethal doses of living rabies virus ; control animals in every case died from rabies ; the two vaccinated animals that developed rabies did so later than the control animals, thus showing that they had a greater, though still insufficient, resistance. The serum of these eight animals was tested as to its rabicidal properties ; samples of blood were taken (previous to their being inoculated with living virus), and after separation of the serum this was mixed with an equal volume of diluted (1 in 200 or 1 in 300) living rabies virus, and incubated at 37° C. for two hours ; after which rabbits were inoculated subdurally with 0·2 c.c. ; at the same time control rabbits were inoculated with a similar mixture of virus and of serum from an *un*treated animal of the same species as the immunised animal ; 12 experiments and 12 controls were carried out ; the rabicidal power was complete in seven and considerable in the other five animals, which developed rabies later than the controls in which normal serum was used. Now, antirabic treatment is essentially prophylactic ; it differs from the preventive measures against other infectious diseases in being only carried out after infection has taken place, but before it has had time to assume an active phase. It is most important, therefore, that, when it is required, it should be commenced as early as possible ; hitherto it has been necessary for an infected person to journey to a Pasteur Institute, where the preparation of a "living vaccine" is carried on, and where this is always available, whether by the "dried cord" method of Pasteur, or the "dilution" method of Högyes ; in either case the fact that living vaccine is used precludes the possibility of sending it to a distance for the treatment of a patient without serious risk of interfering with its efficiency. On the other hand, a dead carbolised rabies virus, such as Sir D. Semple has here described, can be sent to any centre where treatment could be carried out without risk of injuring its properties. One central institute could supply the whole of India with vaccine, patients would be saved long and expensive journeys, and, most important of all, they would come under early treatment, which is of the very essence of success ; a treatment, moreover, free from all risks.

By Lieutenant-Colonel Sir D. Semple, M.D. R.U.I., Director, Central Research Institute, Kasauli. Calcutta, 1911. Price 9*d*.

A REINFORCEMENT OF THE POISONS AND PHARMACY ACT.

LIQUID preparations containing more than 5 per cent. by weight of free ammonia have been prescribed, by an Order in Council, as substances to which Section 5 of the Poisons and Pharmacy Act applies. That is to say, these preparations must not be sold by retail except in bottles distinguishable by touch from ordinary bottles, and unless the bottles are distinctly labelled with the word "Poisonous," the words "Not to be taken," the name of the substance, and the name and address of the seller. The substances to which these

regulations previously applied[1] were sulphuric acid, nitric acid, and hydrochloric acid, and (as to the labels) the soluble salts of oxalic acid. The regulation as to the sale of ammonia will come in force on Feb. 1st, 1912.

RECENT URBAN MORTALITY IN THE UNITED KINGDOM.

THE published results of the recent Census, affording as they do a revised and trustworthy basis for the calculation of rates of mortality, have added interest and value to the statistical returns issued periodically by the Registrar-General. The present population of the 77 large English and Welsh towns dealt with in the Registrar-General's weekly returns is now estimated at 16,157,797, and is less by rather more than a million than the estimate previously based upon the rate of increase that prevailed between the two preceding Census enumerations in 1891 and 1901. The effect of this over-estimate of the population of these 77 towns was to understate the recently reported mean annual death-rate in the aggregate of these towns by about 1 per 1000. Calculated on the now revised estimate of their population, the mean annual death-rate in these English and Welsh towns during the 13 weeks of the past spring quarter (ending on July 1st) was equal to 13·8 per 1000. In the corresponding period of last year the recorded death-rate, calculated on the over-estimated population, did not exceed 12·6 per 1000. If, however, the unprecedentedly low death-rate in these 77 towns during the spring quarter of last year were corrected for the over-estimated population, the corrected rate would be but slightly below that recorded during the corresponding period of this year. The annual death-rate from the principal epidemic diseases in these towns during last quarter scarcely exceeded the corrected rate from the same diseases in the corresponding period of last year, notwithstanding the somewhat exceptional prevalence of measles in many of the large towns during last April and May. The death-rate of infants under one year in the 77 towns during the past spring quarter did not exceed 96 per 1000 registered births, and corresponded with the low rate that prevailed in the spring quarter of last year. On the whole, the mortality statistics for these 77 large towns during last quarter imply that their mean health-condition was almost identical with that prevailing during the spring of last year, when the death-rate, after correction for over-estimation of the population, was lower than in any previous corresponding period. In the eight principal Scotch towns the population of which is now estimated at 1,710,291, on the basis of the recent Census returns, the annual death-rate from all causes during the 13 weeks of last quarter was equal to 16·7 per 1000, and the rate from the principal epidemic diseases to 2·1 per 1000, owing mainly to the exceptional fatality of whooping-cough; and the death-rate of infants under one year was equal to 110 per 1000 registered births. In the 22 town districts of Ireland, having an estimated population of 1,149,495 (revised on the basis of the recent Census returns) the annual death-rate from all causes was equal to 17·9 per 1000, and from the principal epidemic diseases to 1·3 per 1000; while the death-rate of infants under one year of age did not exceed 95 per 1000 registered births. Thus the annual death-rate from all causes, calculated in each case on estimates of population based on the recent Census returns, showed during last quarter an excess of 2·9 per 1000 in the Scotch towns, and of 4·1 per 1000 in the Irish towns, in comparison with the rate during the same period in the 77 large English and Welsh towns. Thus in equal numbers living there were during last quarter 121 deaths in the Scotch towns and 130 deaths in the Irish towns to each 100 deaths registered in the 77 far larger English and Welsh towns. It is now impossible to ignore such excess in the rate of mortality as conclusive evidence of inferior sanitary condition and administration.

[1] THE LANCET, April 1st, 1911.

THE annual luncheon of the Continental Anglo-American Medical Society will be held in Birmingham on Thursday, July 27th, at 1 30 P.M., at the Grand Hotel, Colmore-row. The chair will be occupied by Sir William Osler, Bart., Honorary President. Members of the society who intend being present are requested to communicate as soon as possible with Dr. Charles G. Jarvis, honorary secretary, 81, Boulevard Malesherbes, Paris.

WE regret to announce the death on Monday, at the age of 69 years, of Mr. Henry Ebenezer Allen, B.A., LL.B., late Registrar of the General Medical Council and Clerk of Convocation of the University of London.

METROPOLITAN HOSPITAL SUNDAY FUND.

WHAT IS NON-INFLAMMABLE FLANNELETTE?[1]

THE question of the danger arising from the use of flannelette for articles of clothing was one of the subjects of inquiry referred to the Coroners' Committee by the Secretary of State for the Home Department in December, 1908. The committee issued a separate report on this particular question on August 23rd, 1910, and on the whole the members of this committee did not appear to regard the matter in a very serious light. "Legislation of the kind suggested," they concluded, "is the less justifiable in view of the fact that matters may, in course of time, be expected to right themselves. Great improvement has already been made in the manufacture of flannelette and further improvements may be anticipated. There is also the possibility that new and cheaper methods of diminishing the inflammability of the material may be discovered. ..... Having regard to these considerations, we are unable to recommend any legislation, except for the case in which there is a positive misrepresentation of the character of the goods offered for sale." But in Clause 7 of the report the committee state that for cases of misrepresentation there is no difficulty in providing. "Nothing more is required than to amend the Merchandise Marks Act, 1887, by adding a provision making it penal to describe as uninflammable material which will not stand certain prescribed tests. A proposal to this effect has been made by some of the witnesses, and we have no hesitation in recommending it for adoption." On the face of it the proposal seems perfectly reasonable, but as far as we can gather it has not received legislative sanction or acknowledgment, which it obviously should do assuming that such misrepresentation exists, and having regard to the real dangers to which such a deception might easily lead.

Our attention was drawn to this aspect of the question by the National League for Physical Education and Improvement, and on that body assuring us that such a state of things did exist we offered to undertake an experimental inquiry into the matter, the samples of material to be obtained by the League and to be forwarded to THE LANCET Laboratory for testing purposes without any intimation at all being given to us as to where they were procured or as to the name of the manufacturer. All the manufacturers of flannelette, as far as was known by the League, whose goods were advertised as being safe, were informed of the intention to submit the materials to fire tests, and were invited to send samples. A dozen pieces of material were eventually sent to us by the League, six coming from two of the manufacturers and six having been obtained in the open market. Each was marked with a distinctive mark placed upon it by the secretary of the League.

Flannelette is admittedly a cheap substitute for flannel or wool and the material has proved a veritable boon to the poor because of its comfortable and comforting qualities chiefly as an article of underclothing. It is soft and warm to the touch, wears well, and in many ways presents qualities as a material for clothing equal to wool itself, while it is infinitely cheaper. Its use is not by any means confined to the poor, for flannelette garments are now worn and appreciated by all classes. Moreover, flannelette is about half the price of real flannel, or even less, according to the quality supplied. It consists entirely of cotton, the secret of its success as a clothing material being merely the fact that it has a raised surface or nap which forms a kind of cotton-wool coating to the fabric. It is this nap which at the same time forms a source of comfort and a source of danger, the former because of its high non-conducting quality and the latter because of its ready inflammability. Real flannel possesses the double advantage of being warm and insulating and practicably non-inflammable.

In Figs. 1 and 2 illustrations (which are photographs of the material after testing) will be found of the difference in regard to the inflammability of flannelette and flannel before washing and after washing. It will be well to describe exactly how this experiment was performed, as it was applied eventually with the same detailed attention to the series of flannelette fabric submitted to examination and alleged to be "safe."

A piece of fabric 6 inches square was hung upon two fine hooks at the top. The tip of a small conical coal gas flame 3½ cm. long and 3 mm. thick was then brought into contact with the fabric at a point about 1 inch above the lower edge and as nearly as possible in the centre. The contact in every case was 2 seconds; at the expiration of 15 seconds the flame, if it persisted, was extinguished by pressing upon the burning material a pair of cardboard squares. It was felt that this method of testing the material approximated to the conditions of practice when a garment comes into contact with flame. It is quite obvious that a garment never has a fresh clean cut edge at the bottom of it: it is finished always with a hem, the cloth being doubled over and sewn. It is also probable that when contact occurs with

FIG. 1.—Flame test, 2 seconds' contact.

[1] A contribution from THE LANCET Laboratory.

a flame or fire it is rarely if ever immediately under the edge, it is practically certain to be against the surface. Moreover, the garment at the time of ignition is generally, if not necessarily, in an upright position, so that ignition once started proceeds upward to the portions heated already by the advancing flame. In Figs. 3 and 4 it will be seen that when common flannelette is ignited below under a clean cut edge the firing is more extensive than when the flame is applied a short distance above the edge. The former method, in short, exaggerates the inflammability of the material, while the latter more likely corresponds with the actual occurrence of ignition in practice.

Apart from illustrating the way in which the tests were made Figs. 1 and 2 show in a striking manner the inflammability of common flannelette as compared with real flannel. Real flannel, in fact, may for all practical purposes be regarded as non-inflammable. The material only burned so long as the starting flame was in contact, and there was no need to quench the flame after 15 seconds' interval; it went out. Incidentally it will be noted that common flannelette is much more inflammable after it is washed (Figs. 1 and 2). This is a point which will be developed when we come to the series of tests made with a number of flannelette materials said to be "safe."

The materials tested were just a dozen in number, and the results are given in the following paragraphs while certain information supplied in regard to them, and obtained by the League, is added with each description. A brief record of the results of the tests follows, and in each case the experiment is illustrated by a reproduced photograph, Series I. and Series II., of the burnt material.

Sample A, Price 4¾d. per Yard.

The following is an extract from an advertisement of this sample:—"It can be recommended for any purpose for which a high-class flannelette may be used. It is of short and even nap and is absolutely free from any tendency to flare."

Results of tests. — Unwashed the material burned sluggishly, but, as will be seen from the photographs—Series I. (*b*), (*c*), and (*d*)—it became decidedly dangerous even after the first washing, the general effect of washing being to "fluff" the material. The washing was done with soap and water by a person accustomed to washing domestic underclothing. The claim in regard to its non-flaring tendency is not sustained by these experiments.

Sample B, Price 7¾d. per Yard.

The following is an extract from an advertisement of Sample "B":—"A guaranteed fabric, equal to Ceylon flannel in appearance and infinitely superior in washing and wearing qualities, yet only half the cost, is 'B'; the best fabrics for shirts, blouses, and underclothing. Smart designs. Fast colours. Will not flare."

Results of tests.—This material ("B") did not burn vividly, and the flame was inclined to go out before it was purposely quenched in 15 seconds, but it became distinctly dangerous after first washings ("B," Series I. (*b*)) and after subsequent washings (Series I. (*c*), (*d*)) it was distinctly inflammable, and the claim "will not flare" is not sustained by these experiments.

Sample C, Price 6¾d. per Yard.

The following is taken from an advertisement of this material:—"A problem solved. Considerable interest at present attaches to the solution of the question, 'How to make a cotton flannelette at once warm, healthy to wear, and non-inflammable.' The 'C' flannelette possesses the above qualifications in the highest possible degree. ..... It has the further advantage that it raises better and closer, and is therefore less inflammable than an ordinary twilled flannelette. An article made in this manner will not take fire more readily than an ordinary night-dress. Every piece is warranted free from extraneous moisture and from all injurious chemicals. 'C' flannelette has stood the test of time and experience. ..... Being exceptionally short and close in the pile will not easily catch fire and is much safer than the ordinary makes of flannelette. Confidently recommended for all classes of underwear and for ladies' and children's nightdresses."

Results of tests.—The unwashed material ("C") behaved well on placing it in contact with the testing flame, the flame on the material not lasting more than five seconds, going out, that is, before the 15 seconds' interval, when, as in all the experiments, the progress of the flame was stopped by pressing upon the fabric two squares of cardboard on each side. Its inflammability increased distinctly after washing once, but it did not appear to get worse after the second and third washing, the flame tending to converge rather than spread, as the illustrations show (Series I.). The material is a decided advance on ordinary flannelette, and much safer.

Sample D 1, Price 8¾d. per Yard.

The following is taken from an advertisement of Sample D 1:—"The only safe and fire-resisting flannelette is 'D 1,' the cheapest life insurance in the world. It is the only flannelette proved to be safe by a committee of scientific experts; the only flannelette approved by the Home Office Commission. 'D 1' has a standing challenge to the whole textile world which has never yet been taken up, because it is invincible. 'D 1' combines all the advantages of high-class flannelette with a degree of safety possessed by no other. It is cosy, warm, most durable, pleasant to the skin, aseptic, easy to wash, and is flame-proof to the last thread."

Results of tests.—Material "D 1" was practically flame-proof when tested unwashed; it only seemed to burn during contact with flame, and when the flame was withdrawn the flame on the material went out in five seconds, and there was consequently no need to quench it at the 15 seconds limit. Its inflammability, however, increased distinctly after the first washing, but it was never inflammable to a dangerous degree, the flame proceeded unwillingly, so to speak, converging in most instances rather than spreading (Series I. (*c*)). The claims in regard to the safety of this material are established, we think, by our experiments.

Samples D 2, D 3, D 4.

The claims made for these fabrics were similar to those made for D 1, and it will be seen from the illustrations of the tests (Series I. and II.) that they were similarly flame-proof. The unwashed samples declined practically to burn at all. There was a slight tendency, however, to burn after washing, although the flame made a tardy advance and practically went out long before the 15 seconds interval. It will be seen that in these cases the flame converged and showed no inclination to spread. The materials D 2, D 3, and D 4 are therefore probably safe from flame and the claims made in this regard are sustained by our experiments.

Samples D 6, D 7.

These may be considered together, as similar claims are made for them as to flame-proof merits, and they went through the test of flame with very satisfactory results. The unwashed material practically refused to burn, the result of applying the flame for two seconds being merely a charred spot. This slightly extended on a washed specimen, but there was no flame after the contact flame was withdrawn. Both materials are free from fire danger and absolutely safe, and the advertised claims in regard to safety are sustained by our experiments. In spite of their non-inflammability there was a comfortable smooth nap or pile upon these fabrics.

Sample E, Price 6¾d. per Yard.

The manufacturers of this fabric wrote in regard to their goods:—"We do not claim that they are non-inflammable, but that they are as safe as linen, and even safer than calico, muslin, &c. Our flannelettes were thoroughly tested before the Coroners' Committee; we enclose extracts from the record of the proceedings of that committee giving the chairman's description of the tests and his remarks, which show that the committee was satisfied with the result. ..... When we commenced the manufacture of flannelette we speedily realised that if loosely made and with a long nap it offers no resistance to fire. We therefore proceeded upon opposite lines and made our goods with a closely woven foundation with a short close nap which is obtained by a special process. This has been so successful as not only to merit the remarks of the chairman of the Coroners Committee, but no single burning fatality in connexion with 'E' flannelettes has ever been recorded. ..... If the public would refuse to purchase the low-class goods and only use cloths like 'E' flannelette, there would be no danger in any well-regulated household, as in these goods there are no chemicals which can possibly injure the skin of the tenderest child." The above statements occur in effect also in some advertisements of these goods. It is of interest to record, also,

that the assistant at the shop where Sample "E" was obtained said at the time of purchase, "This is quite as good as 'D 1'—it is practically 'D 1,'" while an assistant at another shop said, when safe flannelettes were asked for, "We only keep 'E,' and their 6¾*d.* flannelette is quite as good as 'D 1' at 8¾*d.*"

Results of tests.—An inspection of the illustrations of the flame test in Series II. (*a*), (*b*), (*c*), (*d*) will show that material "E" is decidedly superior to common flannelette, and even on repeated washing the inflammability was not increased. After the third washing the burnt area was no greater than was the case with the original unwashed material, and it will be seen that the flame converged to a point which invariably means that it is going out and not spreading. The makers deserve credit, we think, for their perfectly frank statement that "we do not claim that they are non-inflammable," while they add, "but they are as safe as linen." The statements are in complete accord with our experiments. The material does burn on contact with a flame, but burns sluggishly, and we are inclined to think that materials of the type of "E" may be regarded as reasonably safe. It is not in this regard, however, so completely proof against flame as the material which has been treated with certain fire-proofing materials, and therefore it is not correct for a shop assistant to describe, as was the case, "E" material as safe as a material so treated. The question of fire-proofing will be discussed further on.

Sample F 1, Price 8¾d. per Yard.

The following is taken from an advertisement of this material:—"The safest substitute for flannel. Non-flashable, healthy, pure, warm and safe." A press opinion of this

material is quoted as follows:—"It is highly satisfactory to meet with a home-manufactured fabric that is absolutely non-flashable. ..... F 1 claims these qualities and is in every way equal to flannel."

Results of tests.—The photographs of the material submitted to the flaming test described, Series II., show that it is decidedly inflammable, but its inflammability does not appear to increase after washing. An exception to this occurs in row (*d*), in which the fabric is seen to have flared badly. In these circumstances we cannot regard the material as "safe."

Sample F 2.

This was sent in by the manufacturers in response to an invitation to do so. They made the following statements amongst others in regard to the fabric: "We wish specially to point out to you that we do not claim any specially fire-resisting qualities for this cloth, but what we do claim is that it is not dangerous as regards fire. It is made wholly of cotton which is a combustible article. The object we had in front of us when bringing out this cloth was to produce a material that was not dangerous. Should the cloth come in contact with a flame it would not instantly become alight from end to end, and in fact would not burn any quicker than ordinary plain calico. ..... We think we can claim for this cloth that it does not flash. That it will not burn too readily. That should it get alight it is easily extinguished; that should a lighted match be thrown on the cloth it does not flame but singes; that it is quite as safe as any ordinary calico, whilst in addition it has more warmth and is more comfortable than calico."

Results of tests.—It will be seen that when the original unwashed specimen of this cloth was subjected to our test

the flame was not a serious one, it converged almost to a point, and did not spread. In fact, the flame very nearly went out. But as soon as the washed fabric was experimented with the flame showed serious dimensions and progress. In row (*d*) in particular the result showed a spreading and upward progress of the flame. We think that the results of these experiments hardly justify us in saying that the material may be counted upon as safe.

Summary of Results.

It will be seen that out of the 12 specimens of fabric tested 7 may be classed as undoubtedly safe, 4 must be classed as unsafe, and 1 as doubtful. The "doubtful" one and the "unsafe" ones owe this classification, we think, to the fact of their increasing tendency to flare when the material is washed. The effect in this way of washing may be due to fire-proofing substances being removed or to a "fluffing" of the fabric, the washing process tending to loosen the fibres. The question whether fire-proofing materials are employed to render the fabric safe receives light by the determination of the mineral matter in the washed and unwashed fabric.

In the table given below will be found the mineral constituents of the fabrics which were tested as regards their inflammability by the method above described. The results show the percentage amount of mineral matter or ash remaining upon a clean incineration of the fabric both before and after washing.

Table Showing the Mineral Constituents of "Safe" and "Unsafe" Flannelette before and after Washing.

Fabric.	Original ash.	Ash after washing.	Percentage of residual ash.	Percentage of ash washed out.	Classed as "safe," "unsafe," or "doubtful."
A	5·61	0·21	3·75	96·25	Unsafe.
B	2·41	0·18	7·50	92·50	,,
C	2·18	0·81	37·16	62·84	Doubtful.
D 1	11·49	9·83	85·56	14·44	Safe.
D 2	11·69	7·66	65·53	34·47	,,
D 3	12·49	9·00	72·00	28·00	,,
D 4	18·73	8·86	47·30	52·70	,,
D 6	20·77	17·50	84·26	15·74	,,
D 7	21·35	15·15	70·20	29·80	,,
E	0·68	0·52	76·50	23·50	,,
F 1	8·86	0·20	4·50	95·50	Unsafe.
F 2	1·87	*Nil.*	*Nil.*	100·00	,,

It will be seen that there is an enormous variation in the amount of ash in different flannelettes. As a minimum the figure 0·68 per cent. is given, and as a maximum 21·35 per cent. The series marked by the letter "D" are all evidently flame-proofed by mineral material, and it is interesting to notice that with the increase of this loading so does a reduction occur in inflammability. As examples of this may be quoted the materials "D 6" and "D 7," Series II., which as regards non-inflammability give the most favourable results, but more particularly on washing, there being little if any increased tendency to burn, even after a third washing with soap and water. There can be little doubt, therefore, that "safety" can be obtained by impregnating the fabric with certain mineral salts, but when their amount reaches one-fifth part of the fabric it may well be asked whether this does not interfere with what may be called the "cloth-like" character of the garment. At any rate, it adds to the cost of the fabric, while it is conceivable that the insulating power of the cotton fabric is reduced. The mineral salts used appear to be present in real combination with the cellulose of the fabric, so that it is hardly likely that they would affect the wearer injuriously, and a long practical trial by wear of such treated material would appear to support this view, no irritating effects or harm to the health having been experienced over the experimental period. It has been suggested that the public should be enjoined to do the fireproofing for themselves by means of such substances as alum or borax, but common sense dictates the hopelessness of such an appeal. We may accept the evidence given before the Coroners' Committee in regard to the improbability of the poor women, whom the matter most concerns, going to the expense and trouble of using fireproofers as often as any article has been washed, besides which the question of the harmlessness of uncombined alum or borax next the skin is open to doubt.

An alternative method to fireproofing the fabric by the impregnation of metallic salts has evidently engaged the attention of flannelette manufacturers since the dangers of flannelette were brought into painful public prominence. This consists in reducing the looseness of the fabric and the nap or pile, which, as we have already pointed out, is the dangerous starting-point of a conflagration. A surface of loose cotton-wool, so to speak, burns with the facility and fierceness of spirit of wine. A close nap and a closely woven foundation seem to us to be a very desirable aim, and we have evidence in front of us that very valuable advances have been made in this direction. We have examined fabrics, at at events, which, according to some of the experiments above recorded, showed a very considerable improvement upon ordinary flannelette in regard to a reduced tendency to ignite, and yet which were not fireproofed by minerals. It is not possible to say, however, that these materials are at present as trustworthy in regard to safety from fire as the fabrics which are fireproofed by well-known fireproofing agents, for even the nap or "fluff" of the fireproofed material fails to catch fire on contact with a flame. We are in entire agreement with two conclusions of the Coroners' Committee, that (1) "great improvement has already been made in the manufacture of flannelette and further improvements may be anticipated," and that (2) "there is also the possibility that new and cheaper methods of diminishing the inflammability of the material may be discovered."

The present position is, however, unsatisfactory, for it is clear from our investigation that not only is flannelette still sold at large with no pretensions to being non-inflammable, but flannelette is sold also to the public which wrongly claims to be non-inflammable. This should be, it seems to us, a matter for immediate legislation, and we fail to understand why, in view of the strong recommendation of the Coroners' Committee to make penal the false description of an inflammable material, the matter has not been brought by the State promptly within the operations of the Merchandise Marks Acts. It should be remembered that all this time the matter is being discussed the number of victims to the inflammability of flannelette does not diminish. There is evidence, in fact, of an increasing toll.

ROYAL SOCIETY OF MEDICINE.

Annual General Meeting.

THE annual general meeting of the Royal Society of Medicine was held at the society's (temporary) house, 15, Cavendish-square, W., on July 7th, Sir HENRY MORRIS, Bart., the President, being in the chair.

The Report of the Council.

Dr. ARTHUR LATHAM, senior honorary secretary, read the report of the council for the year 1910–11. This showed that the membership of the society was now—Fellows, 2327; and members of sections, 919. Good progress was reported in the building of the society's new house, which was commenced on Dec. 1st, 1910, and which the builders are under contract to complete by December of this year. The finances of the society should be in a wholly satisfactory condition provided that the amount required for the new building was subscribed. The donations to the building fund were as follows: Received, £8982; promised, £2356; debentures presented, £1450; total, £12,788. The amount still required is over £17,000.

In the honorary treasurers' report to the council presenting the income and expenditure account for the year ending Sept. 30th, 1910, the treasurers note that the subscription income continues to increase. This amounted during that year to £8183 11*s.*, as against £7958 1*s.* 4*d.* for the preceding year. On the expenditure side there has again been a large increase, in great part due to the rent (at the rate of £800 per year) payable for temporary premises, 15, Cavendish-square, and to the amount paid for the use of meeting-room at 11, Chandos-street. The cost of the Proceedings was £2345 19*s.* 5*d*, being £247 2*s.* 6*d.* less than in the previous year. £965 17*s.* were spent upon the purchase and binding

of books and periodicals for the library, a diminution of £107 2s. 1d. The credit balance amounted to £202 6s. 5d.

The honorary librarians' report to the council shows that the work in the library during the past year has been satisfactory. 2537 books and pamphlets have been added. Of these, 691 are volumes of periodicals taken regularly and 305 are purchases, including nine periodicals which are new, or were needed for the completion of sets. The remaining 1541 are donations, including some duplicate sets of periodicals and pamphlets already in the library. 808 volumes have been bound. The number of readers has been 6693, a slight falling off from last year, which is probably accounted for by the cramped accommodation in the society's temporary house. The number of books borrowed has been 6805, and is about the same as in previous years. The report closes with the satisfactory news that Mr. J. Y. W. MacAlister, the secretary of the society, is recovering from a serious operation which he has recently undergone.

Sir WILLIAM S. CHURCH, Bart., K.C.B., senior honorary treasurer, explained the accounts, and the following motion was then carried unanimously:—

That the report of the council for the year 1910–11, together with the audited annual accounts for the year 1909–10, be received and adopted.

The following were elected officers and members of council for 1911–12:—President: Sir Henry Morris, Bart. Vice-Presidents (being the Presidents of the various sections): Dr. W. J. McCardie (Anæsthetics), Mr. G. H. Thompson (Balneological), Dr. G. A. Sutherland (Children), Sir William Osler (Clinical), Sir Malcolm Morris (Dermatological), Mr. Archibald D. Reid (Electro-Therapeutical), Dr. Theodore Thomson (Epidemiological), Dr. StClair Thomson (Laryngological), Dr. Frederick Taylor (Medical), Dr. F. W. Mott (Neurological), Dr. Amand Routh (Obstetrical), Mr. H. Lloyd Williams (Odontological), Dr. W. Milligan (Otological), Dr. R. T. Hewlett (Pathological), Mr. Clinton T. Dent (Surgical), and Dr. W. E. Dixon (Therapeutical). Honorary treasurers: Sir William Selby Church, Bart., and Sir Francis H. Champneys, Bart. Honorary librarians: Mr. Rickman J. Godlee and Dr. Norman Moore. Honorary secretaries: Dr. Arthur Latham and Mr. Herbert S. Pendlebury. Other members of council: Sir William Allchin, Dr. R. A. Gibbons, Mr. J. Warrington Haward, Dr. W. P. Herringham, Mr. R. Clement Lucas, Mr. D'Arcy Power, Dr. H. D. Rolleston, Mr. Charters J. Symonds, and Mr. E. F. White.

Mr. F. W. Lord, chartered accountant, was re-elected auditor to the society for the year 1911–1912.

Presidential Address.

The PRESIDENT then addressed the meeting on the work and prospects of the society. He referred to the difficulties with which the work had been carried on owing to the cramped space in the temporary premises at Cavendish-square; of the 118 meetings 42 had been held in the rooms of the Medical Society. On account chiefly of the difficulty of obtaining a suitable room no general discussion of the society had been held during the present year. Many of the sections, however, had had meetings, at which discussions of general interest had been held; among these he mentioned discussions on Syphilis in Relation to Otology and on Injuries of the Ear by the Otological Section; discussions on Fractures in the Neighbourhood of the Joints, on the Treatment of Cleft Palate, and a meeting was devoted to papers on Traumatic Myositis Ossificans by the Surgical Section; a discussion on Cæsarean Section and its Alternatives by the Obstetrical and Gynæcological Section; a discussion on Albuminuria in Adolescence by the Medical Section; the Samuel Hyde Memorial Lectures by the Section of Balneology and Climatology; and a discussion on Frontal Sinus Suppuration by the Laryngological Section. With regard to the new building there was every prospect that it would be completed by Dec. 1st next, this being the date fixed by the contract with the builders. Sir Henry Morris hoped that the deficiency of £17,000 on the building fund would be made up before the opening of the new building. If not, it would be necessary to borrow the sum, and though the society would not in that case be in financial straits, as the interest on this sum would be counterbalanced by the saving in rent, which was now paid for the temporary premises, yet the society would be hampered in providing many of the advantages for which it was instituted. For instance, in addition to the fine lending library now owned by the society provision of a standard reference library was obviously of the first importance. It would be a great boon to Fellows, too, if it could be found possible to arrange that they might be provided, at request, with abstracts of papers, &c.; this privilege was already given to Fellows residing abroad, and had been much appreciated by them. Altogether, then, he thought it might be said that the work of the society was being maintained at a good level, and no one could doubt the great usefulness and distinction of the services which the society rendered. Under those circumstances, it was gratifying to know that in a very few months they would be in a building worthy of the society, of its distinguished national and metropolitan position, and of the character and importance of the work which it carried on. At the same time, however, money was wanted, the occasion was exceptional, and the opportunity was very fitting to ask all Fellows and Members to do what they could to secure that measure of pecuniary support which would enable the society to be placed in a firm and sound financial position. He felt sure there were a large number of Fellows and Members of the society who could, if they would, render very material assistance at this juncture, and who probably by their personal influence upon others who were not members of the profession might induce them also to give the society support. Nobody could deny that there were good grounds for asking those outside to assist a large institution of national and scientific importance such as the Royal Society of Medicine, and they were not exceptional in taking that course. During the last few days the Royal Geographical Society had put forth, through its distinguished President, a claim for support, not only from Fellows of the society, but also from the friends of the society and from the over-sea members of this empire who were in this country at the present moment. Lord Curzon pointed out that although there were 5000 Fellows in the Geographical Society, most of them were not wealthy and had therefore appealed to the public to come forward to assist that society. There were many reasons why the Royal Society of Medicine, which was a national as well as a metropolitan institution of a very marked and useful order, should do the same. But Sir Henry Morris pointed out that to the Fellows and Members of the society must they look chiefly for the money to wipe the deficit off their present building fund.

The meeting closed with a unanimous vote of thanks to the retiring Vice-Presidents.

THE VALUE OF SANATORIUM TREATMENT.

WE are indebted to the Executive Committee of the Welsh National Memorial to King Edward VII. for the following memorandum on the functions of sanatoria which has been prepared at their request for general circulation in the Principality:—

"The public has formed a wrong impression of the value of sanatorium treatment, for it has not grasped the facts which prove that, in many cases, owing to the severity of the disease present, it must be useless; that in a few instances it is actually harmful; and that in may cases this method of treatment need not be carried out at an institution. Again, a number of people are under a misapprehension as to the meaning of sanatorium treatment. In many quarters it is considered to be synonymous with an existence under open-air conditions, together with an excessive supply of nourishing food. Fresh air and food play an important part it is true, but the cardinal factor in the treatment is the constant and skilled regulation of the amounts of rest and exercise prescribed from day to day for each individual patient.

"In order that these misapprehensions may be cleared away it is necessary to point out what takes place during the arrest of consumption in a given patient, and what are the principles of treatment. Consumption, as is well known, is due to the presence of minute organisms—called tubercle bacilli—in the lungs. The only protection we have against these invaders is what may be termed comprehensively the defensive forces of the body. What these forces are we do not exactly know, but they have representatives in the blood and other fluids of the body, the tissue cells, the blood cells, &c. There is no drug which has a specific action upon

tuberculosis. The vaccine known as tuberculin has a specific action, but there are a number of limitations to its power; one which may be mentioned here is that in many cases of consumption we have to deal not only with the tubercle bacillus, but also with other organisms against which tuberculin exerts no protective action."

"The defensive forces of the body successfully combat and defeat the tubercle bacillus in an overwhelmingly large proportion of cases. That this is so is shown by the result that practically every man or woman over 35 bears evidence—available after death—of having suffered from tuberculosis. In the vast majority of these cases the tubercle bacillus has been routed, and this even without the individual ever knowing that he has contracted the disease.

"What determines whether the defensive forces or the bacilli are to prove victorious? Naturally the defensive forces must be put in the best possible condition to fight. They require a constant supply of pure fresh air. Wind should also be avoided, as it increases the tendency to cough. Again, the defensive forces require a proper supply of good nourishing food with sufficient fatty food, such as milk, cream, butter, potatoes, &c., together with a careful regulation of the digestive processes. These requirements do not of course in themselves necessitate a sanatorium, but, in the majority of cases amongst the working classes, it is difficult to provide them except in such an institution.

"The chief reason which makes treatment in an institution a necessity is the need for constant supervision. This can only be explained by a consideration of certain pathological processes. The bacilli manufacture a poison called tuberculin. This poison has a local effect on the lung in which they are present, causing destruction of tissue and so leading to cough, expectoration, blood-spitting, and the signs detected by the stethoscope. The local action of the poison also stimulates a response from the local defensive forces. A more important fact is that some of the poison manufactured by the bacilli is absorbed by means of the lymph stream into the general circulation of the blood. If this poison in the blood-stream is in excess of the powers of the defensive forces of the body to deal with, it leads to lassitude, loss of appetite, loss of weight, sweating, and fever.

"If the dose of poison absorbed is a small one the defensive forces of the body are stimulated to attacking the bacilli. They go to the seat of conflict, surround the bacilli, and, as the result of repeated stimulation by further small doses of poison, eat up the weakened bacilli, and so in time arrest the disease. If the dose of poison is a larger one than the defensive forces can deal with, the latter are overpowered; the bacilli are left in command, multiply, cause the disease to spread in the lung and pour out more poison, which, as already said, leads to fever, sweating, loss of weight and appetite, and all the distressing symptoms of advancing consumption.

"Treatment must obviously be directed, then, to keep the dose of poison absorbed from the diseased area into the blood at such an amount that it stimulates and does not paralyse the defensive forces of the body on which we are so dependent. The amount of poison absorbed depends in large part upon the amount of lymph and blood which goes through the diseased portion of the lung in a given time. A larger quantity of lymph and blood must automatically sweep out a larger quantity of poison. The quantity of lymph and blood which goes through the lung in a given time depends largely on the physiological law that the more work an organ has to do the greater must be its supply of blood and lymph. If a lung moves more than usual, as in coughing, it receives immediately a larger supply of blood. If a man walks several miles, more blood and lymph will go through his lung, and consequently, in the case of a diseased lung, more poison will be swept out than if he lay quietly on a sofa during the same period of time. Movement therefore determines the quantity of blood and lymph which goes through the lung; this in turn determines the amount of poison swept into the general circulation, and this again determines the task which the defensive forces have to meet. In treatment, therefore, if the bacilli are not to be allowed to spread, and the disease to extend, the amounts of rest and exertion must be carefully and constantly regulated according to the ever-varying symptoms of the patient.

"It follows that in all cases of consumption where the dose of poison absorbed is capable of being in excess of the powers of the defensive forces—that is, in the majority of such cases in the class chiefly affected by the Insurance Bill—constant skilled medical supervision is only possible in the institution which is usually called a sanatorium. It also follows that this constant supervision is not so essential in cases in which the defensive forces are fully capable of dealing with the poison absorbed into the general circulation. Cases of consumption may be roughly divided into four classes.

"*Class 1.*—Those patients who become infected and recover without knowing that they have been infected. In these the dose of poison absorbed is practically never beyond the capacity of the defensive forces, and so acts as a stimulant.

"*Class 2.*—Those who would recover if given a holiday at the seaside or some measure of outdoor treatment. In these cases the defensive forces want assistance. The insanitary conditions, want of food, &c., under which the patient lives diminish the capacity of his defensive forces and so enable the bacilli to make further inroads. When the patient is removed from these devitalising conditions his defensive forces automatically become able to fight better, and to deal adequately with such doses of poison as may be absorbed. Consequently, in such cases, were we in a position to gauge the exact condition of affairs, treatment in a sanatorium would be unnecessary. This in the majority of instances we cannot do. It is the best policy, therefore, to send such cases to a sanatorium in the first place. When such supervision is possible, the duration of treatment will, of course, be much shorter than in the case of those who properly come under Class 3.

"*Class 3.*—Those who need careful treatment in a sanatorium. In this class the dose of poison is generally greater than the capacity of the defensive forces, and therefore the amounts of rest and exercise to be taken require constant supervision.

"*Class 4.*—Those who are going to die from infection, whatever may be done for them. This failure is probably due to (1) the incapacity of the defensive forces to respond; (2) the excess of the absorbed poison even in absolute rest is beyond the capacity of the defensive forces. These conditions can be ascertained only after skilled and close observation.

"It is clear, then, in the treatment of cases of consumption in which recovery is not going to occur spontaneously, the defensive forces require careful nourishment in the shape of fresh air and good food, and, above all, the amount of rest and exertion must be carefully regulated from hour to hour. It does not require much thought to see that, in a national campaign dealing with persons whose income is below £160, treatment in efficient sanatoriums is a vital necessity. It is asserted that tuberculin, used in dispensaries for patients who continue to work, gives results as good or better than treatment in a sanatorium. Treatment by tuberculin in Class 1 or in Class 2 is well known to give excellent results, but so does practically any other form of treatment. In Class 3, where doses of poison are on the whole in excess of the capacity of the defensive forces, tuberculin cannot safely be used except under *constant* supervision. If the regulation of the absorption of a man's own poison—his own tuberculin—requires constant supervision it follows that the administration of prepared tuberculin requires the same close observation.

"The success of the so-called tuberculin dispensaries rests largely on the fact that Class 1 and Class 2 are chiefly treated at them. A further part of their success is due to the many instances in which the diagnosis of the presence of active disease is faulty, with the result that many persons are treated with tuberculin and labelled as cures, in whom the disease has previously been arrested. The fact that the physicians attached to the hospitals for diseases of the chest send their patients to sanatoriums is a strong testimony to their usefulness, for it is much more lucrative to the physician to give tuberculin than to send patients to be treated elsewhere. Of the value of tuberculin there is no question. Its use is of great value, not only in Class 2, but also in Class 3—i.e., in patients who require sanatorium treatment. We come, therefore, to the conclusion that neither sanatorium treatment nor tuberculin should be depended upon solely, but that both should be used under conditions which facilitate the closest supervision.

"If sanatorium treatment has not hitherto met with universal acceptance as efficacious in a campaign against consumption, the mistrust is due to a number of causes. In the first place, the majority of existing so-called sanatoriums are inefficient, and the treatment given is not 'sanatorium treatment,' but a treatment in an institution labelled a sanatorium, and consisting of little more than fresh air and abundance of nourishing food, but without adequate medical supervision and the necessary regulation of rest and exercise. The results obtained by these inefficient sanatoriums have been regarded by the public, and by many members of the medical profession, as the results of efficient sanatorium treatment, and have done much to discredit it. The second reason is that sanatorium treatment has been asked to do the impossible, and has been regarded in some quarters as sufficient in itself and as a certain cure for every case of consumption. No responsible member of the medical profession, no level-headed layman, has ever regarded the treatment in this light. The sanatorium is an important link, but only a link, in a comparatively long chain. Unless it forms a part of a carefully thought out system, embracing amongst other things dispensaries, hospitals, homes for advanced cases and the dying, careful disinfection, and after-care of patients when they leave the sanatorium, together with assistance to the breadwinner's family whilst he is under treatment, it cannot help us much to eradicate consumption. Even sanatorium treatment does not cure all forms of pulmonary tuberculosis, and we can scarcely anticipate that any form of treatment ever will prove very efficacious in advanced and long-standing disease. Is it fair to condemn sanatorium treatment because it cannot accomplish the impossible? Again, if a working man in an early stage of consumption is sent to an efficient sanatorium there is every prospect of the disease being arrested; but if he is allowed to return to those conditions under which he contracted the disease—hard work, bad air, insufficient food—the disease will almost certainly relapse. Is it fair when this happens to say that sanatorium treatment is of no avail?

"The third reason is the fact that in the past the erection and maintenance of sanatoriums have cost far too much. This objection no longer holds, as, apart from the cost of land, a sanatorium of a permanent character can be erected and equipped for a little over £100 a bed. The cost of maintenance and administration should amount to rather less than 25*s.* a week per patient. The fourth reason has been the difficulty of making such arrangements for maintaining the family when the breadwinner is away, that the patient may be persuaded to go to a sanatorium early enough, and to stay long enough. Much of the difficulty, however, should be swept away by an intelligent administration of the Insurance Bill.

"Sanatorium treatment, as a link in a chain, confined to those who are capable of being cured within a reasonable period, and supervised by a competent and special trained medical man with administrative capacity, is one of the most valuable offensive weapons we have to-day in our fight against consumption. We have shown that its value in the past has been obscured for several reasons—the inefficiency of many sanatoriums, improper selection of cases, inadequate length of treatment, inadequate 'after-care,' and the like. In the future most of these defects should be removed by efficient administration. In the past many men did not apply for treatment because they knew there was no likelihood of it being obtained in time, as the sanatorium accommodation was insufficient for more than about 1 per cent. of the consumptive population. Under the new Act there should be much greater accommodation; and this in itself should do much to secure treatment in the earlier stages of the disease, and to rehabilitate sanatorium treatment in the opinion of the general public."

NEW NURSING HOME FOR EDINBURGH.—The subscription list opened for the building of a nursing home for patients of limited means has been most cordially supported. The sum required is £10,000, and of that amount £8640 8*s.* 11*d.* have been now subscribed.

FIFTY-THIRD ANNUAL REPORT OF THE GENERAL BOARD OF COMMISSIONERS IN LUNACY FOR SCOTLAND.[1]

Total Number of Insane.

ON Jan. 1st of the present year there were, exclusive of insane persons maintained at home by their natural guardians, 18,636 persons of whom the Board of Commissioners had official cognisance. On Jan. 1st, 1910, the number was 18,337, so that an increase of 299 has taken place during the past year. These figures include inmates of training schools for imbecile children and criminal lunatics. Among registered lunatics—that is, not including inmates of schools or criminal lunatics—there was a total increase of 267, of which number 13 were private patients and 254 were pauper patients. In the Criminal Lunatic Department of Perth Prison there were three more patients than last year and in the training schools there were 29 more children. Decreases among pauper lunatics, amounting in all to 58, have occurred in 11 counties, while increases, amounting in all to 312, have taken place in 27 counties or urban areas. The decreases are distributed among counties with falling populations, while the increases have mainly occurred in industrial counties with increasing populations. It should be noted that the increases are not necessarily due to a larger number of patients being sent to asylums, for they are equally certain to arise through accumulation whenever a falling off occurs in the number of the discharged.

Admissions.

The total number of persons admitted to asylums and other establishments, excluding transfers, was 3312. The number admitted to private establishments was 506, being 10 more than in the preceding year, but 53 less than the average for the years from 1905 to 1909 The number of pauper patients admitted was 2806, being 53 more than the number during the previous year, and 84 below the average for the years 1905 to 1909. With regard to the admission of voluntary patients, the Commissioners are able to state that nothing has occurred to indicate any disadvantage traceable to their presence in asylums, and they continue to be of opinion that it is a useful provision of the law which permits such persons to place themselves under care. At present the process whereby patients can be admitted, although simple, involves a certain amount of delay, which has resulted on more than one occasion in serious consequences, and the Commissioners are therefore in favour of a change in the law which would permit of a person being received into an asylum and being kept there for three days on his own written application to the superintendent, provided that the sanction of the Board be at once applied for in the usual way on admission, and that no voluntary boarder be retained for any longer period than three days without such sanction.

Discharges.

During the year 1910 there were discharged recovered 215 private patients—that is, 14 below the average for the five years 1905–09. The number of pauper patients discharged recovered was 1031, which is 120 less than the average for the five years 1905–09. It appears that during the last 30 years, while the proportion of recoveries among private patients has varied from year to year, it has shown no certain indications of falling off. Among pauper patients a continuous decrease is recorded. The Commissioners are of opinion that the recovery rates have in recent years been unfavourably affected by the increased use of observation wards connected with the parochial hospitals of several large parishes which receive persons suffering from passing attacks of mental disorder, of whom some, in the absence of these wards, would have been admitted to asylums and would have been discharged recovered shortly after admission. The lowering of the rate is further to be ascribed to the accumulation of chronic patients and to the fact that the development of nursing and the improved means of hospital care in asylums have led to their being more freely used for the reception of patients whose age and whose

[1] London: H.M. Stationery Office. Price 1*s.*

mental and physical condition are such as to preclude hope of recovery.

The number of private patients discharged unrecovered was 112, which is 37 less than last year and 25 below the average of the five years 1905–09. The number of pauper patients discharged unrecovered was 375, which is 6 more than the number so discharged in the preceding year and 35 less than the average for the five years 1905–09. The proportion of patients discharged unrecovered to the average number resident has been steadily falling for the past 26 years and last year reached its lowest point. With a falling admission-rate and an increased death-rate this is a matter to be regretted, as the resident population of asylums ought to have fallen rather than to have increased, as has on the whole been the case. There is reason to believe that the cause may be sought in the fact that the general fall in the numbers admitted has either left vacant beds or diminished the pressure upon the accommodation, and has thus removed a strong stimulus towards the discharge of chronic harmless patients. The experience of the Board has shown that there is no greater inducement towards the removal of patients who have ceased to require asylum care than the occupation of beds to an extent which threatens the necessity for further building, and, on the other hand, that there is nothing more likely to cause inactivity in the discharge of patients than the existence of an undue number of empty beds.

Death rate.

The number of private patients who died during the year was 163, which is 46 less than in 1909 and 28 less than the average of the five years 1905–09. The number of pauper patients who died was 1181, which is 3 less than in 1909 and 25 above the average of the five years 1905–09. The death-rate remains at about the level at which it has stood for many years past.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

THE annual general meeting of this association was held on July 6th in the council chamber of the British Medical Association.

The minutes of the last general meeting were read and confirmed. A letter was read from Dr. W. Brown (Bristol) intimating that an invitation would shortly be received from the Lord Mayor of Bristol to hold the next annual meeting in that city. The annual report of the council for the year and the balance sheet were received and adopted. The officers for the preceding year were then re-elected: Surgeon-General G. J. H. Evatt, C.B., President; Mr. D. B. Balding, chairman of council; Mr. A. A. Napper, treasurer; Dr. Major Greenwood, honorary secretary; and Mr. A. Withers Green, auditor.

Dr. MAJOR GREENWOOD then read a paper on the National Insurance Bill and the Poor-law Medical Service, on which an interesting discussion took place. Dr. Greenwood viewed the position of Poor-law medical officers under the Bill with extreme apprehension. He suggested that in some ways even the Minority Report scheme would be preferable. Dr. A. E. LARKING (Buckingham) said he thought the views of Dr. Greenwood were too pessimistic. He thought that the Poor-law Medical Service on the present lines would be improved, and he disagreed entirely with the proposal that it should be made a whole-time service. The agitation about "choice of doctors," in his opinion, was a craze, but he agreed that the policy of the British Medical Association should be strictly adhered to.—Mr. W. HOLDER (Hull) also considered Dr. Greenwood's views too gloomy. If capitation fees were paid for his paupers at the rate proposed by the Bill, he would get about £500 a year. He disagreed with a system of whole-time officers. It was a mistake in the Education Department to have whole-time officers.—Mr. GEORGE JACKSON (Plymouth) said that "free choice of doctors" would not injure the present club medical officers, if they had done their work properly in the past. They would certainly be selected by most of their former patients.—The PRESIDENT thought the National Insurance Bill should not be regarded as being put forward by Mr. Lloyd George, but by the rising democracy, and believed that medical men would not be injured thereby. He said there had been similar denunciations of changes that had taken place in his time in the army, but the army medical officers had come out all right, as would the Poor-law medical officers.—Dr. GREENWOOD said he could not help being pessimistic. The whole profession of the country was so at the present time. Some of those who had spoken seemed to suggest that he favoured whole-time appointments in the Poor-law. He did nothing of the kind. Again, the views of the Minority Commissioners, which he thought should be reconsidered, did not necessarily imply whole-time appointments. They could be worked by part-timers. It was only implied that Poor-law medical officers and sanitary medical officers must be under the same authority. He must confess he had always hitherto consistently opposed such union, but that was before this Bill appeared.

Dr. R. A. LYSTER read a paper on the Organisation of the Poor-law Medical Service and Public Health Service as a uniform institution. He said that treatment and prevention cannot be separated. The medical work now done by Poor-law authorities should be made part of the Public Health work of the district.—Mr. HOLDER supported the view that the Poor-law medical service and the sanitary medical service should be under the same authority. He thought there would be an increase in the number of offices, not a lessening.—Mr. JACKSON pointed out the impossibility of whole-time medical officers in sparsely populated districts.—Mr. T. LLOYD BROWN thought it was not just to speak of the perfunctory character of much of the Poor-law medical work. Similar complaints were made of much of the work of sanitary medical officers. It often happened both in Poor-law and sanitary work the medical officers were practically unable to do anything with the means in their power.—Dr. LARKING did not agree with Dr. Lyster in placing Poor-law medical officers under the sanitary authority. He would keep preventive and curative work absolutely apart, and under different authorities. The Poor-law medical service should be under a Public Assistance authority. There was, further, a great disparity in the number of Poor-law unions and sanitary authorities throughout the country.—The PRESIDENT said he did not agree with Dr. Larking. The mixing sanitary duties with Poor-law would mean extra payment for Poor-law medical officers. Proper sanitary administration was only beginning. He thought it would be much better for a single authority to direct the Poor-law and sanitary medical services. He thanked Dr. Lyster for his admirable paper.—Dr. MAJOR GREENWOOD also considered the arguments put forward by Dr. Lyster to be very strong, and he was glad he had specially emphasised that there was no idea of putting Poor-law medical officers under sanitary medical officers; that they would work together on terms of perfect equality. He must confess he had always been a strong opponent of the single authority plan, being in agreement with Dr. Larking in this matter. The present Bill, however, had made a radical alteration in everything, and it was justifiable to change opinions in the circumstances. He had been very pleased to hear Dr. Lyster's condemnation of a recent proposal of the Local Government Board that part-time medical officers of health should be made whole-timers by having given to them most of the other part-time medical posts now held by general practitioners, such as the Poor-law medical appointment, that of public vaccinator, factory surgeon, police surgeon, and postal medical officer.—Dr. LYSTER, in replying, expressed his appreciation of the way his paper had been received and the sympathy shown for many of his views. He strongly deprecated the notion that there would be any inequality between Poor-law and sanitary medical officers, and, for his part, he would rather serve under a professional principal than a lay one, as was the case of nearly all Poor-law medical officers, who practically were subordinate to the various clerks of the unions.

EXTENSIONS AT ABERDEEN CITY HOSPITAL.—Two open-air shelters for the treatment of tuberculous cases are being erected at the Aberdeen City Hospital. One of these will accommodate 15 male patients, and the other 8 or 10 female patients. Each will have a small dressing-room and bath-room attached. The shelters are of wood on brick foundations. It is hoped that they may be utilised by persons who may only sleep there during the night, going out to attend to their work throughout the day.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

ON July 6th the Fellows of the College had to elect two members of Council. Usually there are three vacancies, but as Sir Henry Butlin, one of those whose terms should have expired on July 6th, is President, he obtains another year of office. Mr. C. T. Dent and Mr. G. H. Makins were the two retiring members of Council and offered themselves for re-election, and Mr. B. G. A. Moynihan of Leeds was also a candidate. 735 Fellows voted by post, and there were seven personal voters; only one voting paper was spoilt, but two arrived too late. The result of the poll was as follows:—

	Votes.	Plumpers.
Mr. G. H. Makins	575	57
Mr. C. T. Dent	401	24
Mr. B. G. A. Moynihan	334	92

At the conclusion the PRESIDENT announced that Mr. Dent and Mr. Makins had been re-elected members of the Council.

The election was peculiar in that there was no real vacancy, for each of the two retiring Fellows offered himself for re-election.

We think it fortunate that both Mr. Dent and Mr. Makins were returned, for they are useful members of Council and have done good work there. Mr. Moynihan, from his position as a surgeon, thoroughly deserves a seat on the Council, and we believe that he would have been returned if a real vacancy had existed. Should he offer himself later as a candidate, we do not doubt that he will be elected.

MEDICINE AND THE LAW.

Rex v. *George Douglas Hay—Guilty but Insane.*

EARLY in June an unusual case of shooting, apparently with the deliberate intent to murder, attracted attention in the newspapers. The victim, Mr. Samuel Splitter, had been riding a motor bicycle near Barnet, but having run short of petrol was pushing it. The prisoner, a stranger to Splitter, riding a bicycle, met him, and after some conversation undertook to ride to Barnet and get him some petrol. Splitter accordingly seated himself by the roadside to wait, when he was suddenly assailed by his new acquaintance, who after striking him on the head produced a revolver and commenced firing at him. Splitter succeeded in escaping and had had enough opportunity for observing his assailant to be able to give a description of a young man named George Douglas Hay, from which he was arrested. The facts as to the shooting were not disputed at the trial at the Old Bailey which has now taken place, the only question for serious consideration being the state of the prisoner's mind when he committed an assault, the bare facts of which, including the absence of any motive or preliminary quarrel, were consistent with mental derangement. The evidence of Dr. S. R. Dyer, medical superintendent of Brixton Prison, was practically conclusive upon this point. He had had the prisoner Hay under close observation and was satisfied that he was of unsound mind at the time of the shooting and that this condition continued. Dr. Dyer was of the opinion that Hay suffered from impulsive homicidal mania, and he produced a remarkable document supplied to him by the prisoner which purported to record his life's history and the progress of his derangement. He was 24 years of age and had been brought up in circumstances which caused Mr. Justice Darling to suggest that he was the illegitimate son of someone who had provided a variety of temporary homes for him during early life. The document in question, which has been quoted at length in the daily newspapers, showed that the prisoner had long led a life of solitude and of close and continual introspection, varied with an attempt at self-treatment for mental malady, of the growth of which he was fully conscious. During the last two years he stated, "so excruciating became the nervous tension when in the presence of other people that I was now driven to carry my revolver with me." Needless to say, he had no difficulty in obtaining and carrying a revolver under a condition of the law against which frequent protest has been made in THE LANCET, and it was good fortune rather than any protection afforded by the legislature which saved Mr. Splitter's life. If Hay had taken an interest in politics and inspired by an insane desire to affect the destinies of his country had shot a Cabinet Minister, or had taken advantage of one of the numerous occasions in which the King and Queen have recently appeared in public, probably a strenuous effort to prevent the carrying of revolvers would have followed, but it might have been too late to avert a national disaster.

Action for Libel by a Medical Man against Another: Pocock v. Hornibrook.

In the London Sheriff's court recently an action for libel brought by a medical man against another member of the medical profession practising in the same district came before the Under Sheriff and a jury for the assessment of damages, the defendant having allowed judgment to go against him by default in the High Court. The plaintiff, Dr. A. R. G. Pocock, had practised at Beaconsfield in Buckinghamshire for nine years, and the defendant, Mr. W. Hornibrook, for five years at Gerrard's Cross. They had been acquainted with one another, and it was stated that at one time the defendant had suggested to the plaintiff, who had declined, that they should enter into partnership. On a more recent occasion, however, Mr. Hetherington, a patient of the plaintiff, called in the defendant to attend a lad in his service; and this the defendant did, but later refused to repeat the visit, and intimated that he wished the fee he had earned to be sent to Dr. Barnardo's home. In the course of a correspondence which followed this incident the defendant wrote one of the libels complained of, offering to double the gift to the institution mentioned if Mr. Hetherington could get an admission from a single medical man in Beaconsfield or Gerrard's Cross, with one possible exception, that he would be willing to attend any patient of Dr. Pocock or to meet that gentleman in consultation. The defendant was represented by counsel, who suggested that he was of an excitable nature, and in addition submitted that the plaintiff had suffered no damage. As, however, the defendant had allowed judgment to go by default in a case in which he had made a serious attack upon the reputation of another medical man in a letter written to a patient of the latter, the jury could not be expected to accept this view, and they assessed the damages at £500. Dr. Pocock's action was undertaken for him by the London and Counties Medical Protection Society, Limited.

Action for Negligence against Sherborne School.

An action of considerable medical importance was heard last week in the King's Bench Division before the Lord Chief Justice and a special jury, when the governors of Sherborne School, the headmaster, and a housemaster were jointly sued for damages by a schoolboy and his father, who alleged that through the negligence of the defendants the boy had lost his right arm. The story in brief is as follows. At the close of the winter term of 1909 the boy, who had always been delicate, was in poor health and contracted a whitlow on the left thumb, which was treated by the matron and by the school medical officer. The boy was allowed to travel home for the Christmas holidays, but on his arrival he was found by the family medical adviser to be suffering from bronchitis. The bronchitis and the whitlow both seem to have disappeared, but shortly afterwards the boy developed symptoms of septic poisoning, and the right shoulder was found to be infected. The shoulder was operated on and subsequently the elbow, and on examination the pus was found to contain a micro-organism common in whitlows. At a further operation necrosis was found, and two days later the right arm had to be amputated. The plaintiffs alleged that the infection which caused the loss of the right arm was due to the negligent treatment which the whitlow had received at school. In support of this the surgeons who operated gave evidence to show that the whitlow was wrongly treated at Sherborne, and that this had caused the subsequent mischief, although it was admitted that no record existed of osteomyelitis following a whitlow. It was claimed for the defence that there was no evidence to show that the boy's subsequent infection could be traced to the whitlow which disappeared in a few days and left no trace afterwards. They asserted that the school medical officer did all that was necessary and proper, that the treatment at school had been correct throughout, and that there

had been no negligence. Mr. Edmund Owen and Professor Sims Woodhead gave evidence that in their opinion the subsequent disease of the right arm had nothing to do with the whitlow on the left thumb, except in so far as both conditions were due to the presence of the same micro-organism. Other medical evidence for the defence was called to prove that the whitlow was subcutaneous and trivial, and that it was correctly treated at Sherborne. The Lord Chief Justice said that the questions for the jury were whether there had been any negligence on the part of the school doctor, the matron, or the housemaster; and if so whether that negligence brought about the loss of the arm? After a brief adjournment the jury answered both the questions in the negative, and the Lord Chief Justice concurred in their verdict, adding that he could not have permitted any other to stand, although he was glad that the matter had been thoroughly investigated. We think that this verdict must meet with the approval of all medical men who have carefully studied the evidence given during the four days' hearing of the action. Also we must all feel deep sympathy with the boy in his irreparable loss. Osteomyelitis is one of the most tragic diseases of early life, and its actual origin is often difficult to determine.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 8169 births and 3715 deaths were registered during the week ending July 8th. The revised estimate of the population of these towns in the middle of this year is 16,157,797 persons. The annual rate of mortality in these towns, calculated on this revised estimate, which had been equal to 11·3 and 11·7 per 1000 in the two preceding weeks, further rose to 12·0 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 13·8 per 1000, and in London during the same period the mean annual death-rate did not exceed 13·2 per 1000. The recorded annual death-rates during last week in the 77 towns ranged from 4·6 in Bournemouth, 5·6 in Aston Manor, 6·9 in Northampton, and 7·0 in King's Norton, to 17·1 in Burnley, 17·6 in Liverpool, 18·4 in Stoke-on-Trent, and 19·4 in Tynemouth. The 3715 deaths from all causes in the 77 towns last week showed a further increase of 92 upon the low numbers in recent weeks, and included 284 which were referred to the principal epidemic diseases, against 273 and 268 in the two preceding weeks. Of these 284 deaths, 87 resulted from infantile diarrhœa, 79 from measles, 54 from whooping-cough, 36 from diphtheria, 19 from scarlet fever, 8 from enteric fever, and 1 from small-pox. The mean annual death-rate from these epidemic diseases was equal to 0·9 per 1000, and corresponded with the rate from the same diseases in each of the two preceding weeks. The deaths attributed to diarrhœal diseases among children under two years of age in the 77 towns, which had been 88, 86, and 70 in the three preceding weeks, rose again to 87 last week, and were proportionally most numerous in Liverpool and in Merthyr Tydfil. The fatal cases of measles in the 77 towns, which had steadily declined in the preceding 17 weeks from 474 to 76, were 79 last week; the highest annual death-rates from this disease recorded in these towns last week were 1·4 in Bolton, 1·6 in Wolverhampton, and 2·8 in Great Yarmouth. The 54 deaths from whooping-cough showed a further decline from recent weekly numbers. The deaths referred to diphtheria, which had been 21 and 35 in the two previous weeks, were 36 last week, and included 14 in London and its suburban districts, 5 in Stoke-on-Trent, 3 in Manchester, and 2 both in Portsmouth and Swansea. The 19 fatal cases of scarlet fever showed a further slight increase upon the numbers in recent weeks; 5 occurred in London, 3 in Liverpool, and 2 both in King's Norton and in Rhondda. The 8 deaths referred to enteric fever corresponded with the number in each of the three preceding weeks, including 2 in London and 1 in West Ham. The fatal case of small-pox was registered in Wallasey. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased in the 12 preceding weeks from 982 to 1226, had further risen to 1264 at the end of last week; 191 new cases of this disease were admitted to these hospitals during the week under notice, against 159 and 163 in the two previous weeks. These hospitals also contained, at the end of last week, 780 cases of diphtheria, 414 of measles, 278 of whooping-cough, and 35 of enteric fever, but not one of small-pox. The 954 deaths from all causes in London last week were fewer by 9 than the number in the previous week, and included 102 which were referred to diseases of the respiratory system, against 139, 111, and 117 in the three preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 136 and 169 in the two previous weeks, declined again to 155 last week; 313 inquest cases were registered. The causes of 25, or 0·7 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during last week were duly certified in London and its suburban districts, Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 50 other smaller towns; the 25 uncertified causes of death in the 77 towns last week included 6 in Birmingham, 5 in Liverpool, and 2 each in Stoke-on-Trent, Leicester, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, with an estimated population of 1,710,291 persons, 885 births and 477 deaths were registered during the week ending July 8th. The annual rate of mortality in these towns, which had been equal to 13·3 and 14·2 per 1000 in the two preceding weeks, further rose to 14·6 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 16·7 per 1000 of the revised estimate of their population, and exceeded by 2·9 the revised mean rate during the same period in the 77 large English towns. The annual death-rate during last week in the eight Scotch towns ranged from 8·7 and 9·3 in Perth and Aberdeen to 16·2 in Glasgow and 19·4 in Greenock. The 477 deaths from all causes in the eight towns last week showed a further increase upon the low numbers in the two preceding weeks, and included 49 which were referred to the principal epidemic diseases, against 64, 58, and 63 in the three preceding weeks; of these 49 deaths, 14 resulted from measles, 14 from infantile diarrhœa, 12 from whooping-cough, 7 from diphtheria, and 2 from scarlet fever, but not one either from enteric fever or small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·5 per 1000; the mean rate last week from the same diseases in the 77 English towns did not exceed 0·9 per 1000. The fatal cases of measles in the eight Scotch towns, which had been 16 and 13 in the two previous weeks, were 14 last week, and included 11 in Glasgow and 3 in Edinburgh. The 14 deaths of infants under two years of age attributed to diarrhœal diseases were fewer by 6 than the number in the previous week; 8 occurred in Glasgow and 3 in Edinburgh. The fatal cases of whooping-cough, which had steadily declined in the five preceding weeks from 43 to 22, further fell to 12 last week, of which 9 were registered in Glasgow and 2 in Greenock. The 7 deaths referred to diphtheria showed an increase upon the numbers in recent weeks, and included 5 in Glasgow. The 2 fatal cases of scarlet fever occurred in Dundee. The deaths referred to diseases of the respiratory system in the eight towns, which had been 51 and 48 in the two previous weeks, rose to 56 last week, but were 10 below the number in the corresponding week of last year. Of the 477 deaths from all causes in the eight towns last week, 151, or 35 per cent., were recorded in public institutions, and 26 were attributed to different forms of violence. The causes of 19, or 4·0 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death during the week did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons (based on the recent Census numbers), 556 births and 312 deaths were registered during the week ending July 8th. The annual rate of mortality in these towns, which had been equal to 13·5 and 17·0 per 1000 in the two preceding weeks, declined again to

14·2 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 17·9 per 1000; the mean rate during the same period in the 77 English towns did not exceed 13·8, and in the eight principal Scotch towns was 16·7 per 1000. The annual death-rate during the week under notice in the 22 Irish towns was equal to 13·9 in Dublin (against 11·0 in London), 12·4 in Belfast, 15·8 in Cork, 8·9 in Londonderry, 16·3 in Limerick, and 28·5 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate last week was equal to 16·5 per 1000. The 312 deaths from all causes in the 22 towns last week showed a decline of 62 from the number in the previous week, and included 22 which were referred to the principal epidemic diseases, against 27 and 21 in the two previous weeks; these 22 deaths were equal to an annual rate of 1·0 per 1000, slightly exceeding the mean rate from the same diseases in the 77 English towns. These 22 deaths from the principal epidemic diseases in the Irish towns last week included 8 from diarrhœa, 6 from measles, 3 from diphtheria, 2 from scarlet fever, and one each from whooping-cough, enteric fever and typhus, but not one from small-pox. The 8 deaths attributed to diarrhœal diseases were all of infants under two years of age, and included 4 in Dublin and 2 in Belfast. The 6 fatal cases of measles were fewer by 3 than those in the previous week; 4 occurred in Dublin and 2 in Cork. Of the 3 deaths referred to diphtheria, 2 were returned in Dublin and 1 in Belfast; and of the 2 fatal cases of scarlet fever 1 each occurred in the same towns. The fatal case of enteric fever was registered in Dublin, and that of typhus in Cork. The deaths referred to diseases of the respiratory system, which had been 48 and 54 in the two previous weeks, declined to 46 last week. Of the 312 deaths from all causes in the 22 towns last week, 94, or 30 per cent., were recorded in public institutions, and 8 were referred to different forms of violence. The causes of 17, or 5·4 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·7 per cent. in the 77 large English towns, and was equal to 4·0 per cent. in the eight principal Scotch towns.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Colonel M. W. Kerin, C.B., principal medical officer of the Bareilly, Garhwal, and Dehra Dun Brigades, has been appointed Principal Medical Officer of the Seventh (Meerut) Division, in succession to Colonel F. B. Maclean. Lieutenant-Colonel M. J. Sexton, at present serving in Dublin, has been placed under orders for duty in South Africa. Lieutenant-Colonel S. C. Philson has been granted three months' leave of absence. Lieutenant-Colonel H. A. Haines has been appointed Senior Medical Officer of the Eastern Coast Defences in succession to Lieutenant-Colonel R. P. Bond. Lieutenant-Colonel J. F. Donegan, from the Military Hospital at Parkhurst, has been selected by the War Office as Recruiting Medical Officer at Woolwich. Lieutenant-Colonel J. M. F. Shine, commanding the Military Hospital at Naini Tal, has been granted leave of absence home from India until Oct. 31st next. Lieutenant-Colonel J. Fallon, in medical charge of the troops at Preston, has been detailed for a tour of service with the Northern Army in India. Lieutenant-Colonel C. E. Nichol, D.S.O., commanding the Station Hospital at Maymyo, Upper Burma, has been appointed to officiate as Principal Medical Officer of the Burma Division. Lieutenant-Colonel C. T. Blackwell has been appointed to command the Military Hospital at Rangoon. Major J. D. Alexander, on completion of a tour of service at Thayetmyo, has been appointed to the Station Hospital at Darjeeling. Major E. W. Slayter, from Wellington, has been appointed to command the Station Hospital at Bellary, Madras Presidency. Major H. E. Staddin, from the Curragh Camp, has joined at Dover. Major E. W. Bliss has been transferred from Mhow to the Station Hospital at Quetta. Major H. G. Martin, from Calcutta, has taken over the command of the Military Hospital at Lebong, Presidency Brigade. Major G. J. Stoney Archer, from Secunderabad, has taken up duty as Specialist in Advanced Operative Surgery at Maymyo, Upper Burma. Major C. W. R. Healey has been granted three months' leave of absence home from India. Major F. Smith, D.S.O., has been granted one year's extension of his Indian tour of service by H.E. the Commander-in-Chief. Major F. J. W. Porter, D.S.O., in medical charge of effective troops at Cosham, has been appointed for duty with the Northern Army in India. Captain J. H. R. Bond, from Mhow, has taken up duty at the Station Hospital, Nasirabad. Captain F. E. Rowan-Robinson, from Colchester, has joined at Norwich. Captain M. B. H. Ritchie has been granted one year's extension of his Indian tour of service. Captain W. A. Woodside, Adjutant of the East Anglian Royal Army Medical Corps School of Instruction at Ipswich, has been placed under orders for duty with the Northern Army in India. Captain C. H. Straton has been detailed for duty as sanitary officer in South Africa. Captain M. C. Wetherell, from Meerut, has joined for duty at the Curragh. Captain T. Biggam has been transferred from Aldershot to Bordon. Lieutenant H. H. Blake, from Allahabad cantonment, has joined the Station Hospital at Peshawar for duty. The following Lieutenants have been detailed for a tour of duty in South Africa: C. T. V. Benson, G. P. Taylor, O. W. McSheehy, C. L. Franklin, J. R. Hill, H. F. Joynt, and H. R. Edwards.

INDIAN MEDICAL SERVICE.

Surgeon-General A. M. Crofts, C.I.E., has been appointed Principal Medical Officer of the Second (Rawal Pindi) Division of the Northern Army in India, in succession to Surgeon-General H. Hamilton, C.B. Lieutenant-Colonel C. E. L. Gilbert has been granted an extension of six months' leave of absence home from India on medical certificate. Major H. Boulton has been recognised as a Specialist in the Prevention of Disease. Major W. Glen Liston has been appointed to officiate in charge of the Bacteriological Laboratory under the Education Department of the Government of India. Captain F. C. Fraser has been appointed for temporary duty in the Madras Presidency. Captain G. A. Jolly has been selected to officiate as Civil Surgeon of Mainpuri. Captain W. D. Wright has arrived home on leave of absence from India. On transfer from Ferozopore, Captain A. F. Babonan has been appointed District Plague Medical Officer of the Ambala District. Captain J. M. A. Macmillan, civil surgeon at Hoshangabad, has been appointed on special deputation duty at Pachmarhi. Captain C. G. Seymour has taken up duty as Specialist in the Prevention of Disease and Charge of the Brigade Bacteriological Research Laboratory at Dehra Dun.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant John J. M. Shaw is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Eastern General Hospital, Royal Army Medical Corps: The undermentioned officers to be Lieutenant-Colonels (dated May 21st, 1911):—Major Edward F. Maynard and Major Frederick J. Paley. The undermentioned officers to be Majors (dated May 21st, 1911): Captain Frank G. Bushnell and Captain Walter A. Bowring. Captain William D. Calvert resigns his commission (dated July 8th, 1911).

Attached to Units other than Medical Units.—Major James Malpas resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated July 8th, 1911).

For Attachment to Units other than Medical Units.—George Bell Brand to be Lieutenant (dated May 15th, 1911).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

Among the many interesting articles in the July issue of this journal is a joint one by Colonel Sir David Bruce, Captain A. E. Hamerton, Captain H. R. Bateman, and Captain F. P. Mackie, I.M.S., on the Trypanosome Diseases of Domestic Animals in Uganda. Captain P. J. Marett writes on the Life-History of the Phlebotomus, the article, which concludes with some suggested measures for lowering the incidence of the "sandfly" fever, being illustrated by drawings which are well reproduced. The subject of marching is one which still

requires much careful investigation, and the thoughtful and suggestive lecture on the Physiology of the March, originally delivered by Lieutenant-Colonel C. H. Melville at the Staff College, and subsequently printed in the *Journal of the Royal United Service Institution*, now finds a place in the *Journal of the Royal Army Medical Corps* where it will receive a still wider publicity which it undoubtedly deserves. Mr. G. G. Nasmith, Ph.D., and Dr. R. R. Graham detail a simple method of treating impure water by means of chloride of lime, which can be used by miners, campers, and others for purifying suspected drinking water on the spot.

Correspondence.

"Audi alteram partem."

THE INCIDENCE OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—The controversies that have ranged round the pronouncement of Koch in 1901 have resulted in the accumulation of a certain and definite amount of knowledge, but it is still uncertain if bovine tubercle—that is to say, if the ingestion of milk or meat derived from tuberculous cattle—can produce human tuberculosis of the lung. In this connexion the facts and figures that can be derived from the tropics have been neglected in a way that seems curious to me, seeing that many hints have from time to time been given in various medical journals showing that the incidence of tuberculous disease in the tropics is very different from what it is in temperate climates; and, in addition to this, the incidence of tuberculous disease in domestic animals in the tropics differs very considerably from what it is in temperate climates. And these two facts bear, I think, on this controversy.

In Perak, or Selangor, and in Pinang, on the authority of the veterinary surgeons of each of those countries, there has never yet been found a single case of tuberculosis in any kind of bovine animal; and cattle-keeping for milking and draught purposes is a very large industry. And according to the annual report of the Director of Medical Research, Kuala Lumpur, for the year 1908, no tuberculosis had been found in any domestic animal.

According to the veterinary surgeon of Pinang, tubercle was found in only 11 pigs out of 62,000 slaughtered, a percentage of 0·017, which is extraordinarily small—so small, in fact, as to suggest that there was none was all. At the Ipoh abattoir, on the other hand, there were no cases of tubercle in the year 1909 out of 35,029 pigs slaughtered—not a single case. These pigs I had every opportunity of seeing; I was searching for tubercle but I could find none.

Now, seeing that about 4 per cent. of all pigs in England are tuberculous, while in Copenhagen in 1897 tuberculous pigs varied from 3 per cent. to 14 per cent., and seeing that inoculation of the guinea-pig was resorted to in none of the Pinang cases, I think it is fair to assume that the real percentage in Pinang was 0·000 and not 0·017—in other words, that tuberculosis does not occur in pigs in this country.

I do not deny the possibility of tubercle occurring in pigs in this country, as there is the possibility of a small number of phthisical pig-keepers who might just possibly infect their pigs with their sputum, but this must be very rare, and as no inoculation experiments have been made in any of the 11 out of 62,000, and as there were no cases of tubercle in 35,000 pigs examined in Ipoh, and as the ratio of tuberculous pigs in tropical countries is so extraordinary, I think that this percentage of 0·017 is open to question. And as it has been shown that the amount of tubercle in pigs is proportionate to the extent of the dairy farming in the country in question (that is to say, that the pigs get their tubercle from tuberculous cattle), and as there is no tubercle in cattle in this country, it would not be expected that tubercle would be found in the pigs of this country.

Now, Dr. Nathan Raw has claimed that the human bacillus of tubercle causes phthisis pulmonalis, secondary ulceration of the intestines, and tuberculous laryngitis; and that the bovine bacillus causes the tuberculous diseases known as acute miliary tuberculosis, tuberculous peritonitis, intestinal and mesenteric primary disease, tubercle of pelvic organs, tuberculous lymphatic glands, tuberculous joints and bones, lupus, tuberculous meningitis, and ulceration of the cornea. This was at a meeting of the Royal Medical and Chirurgical Society, and no one disagreed with him; and I think the experience of this country is quite in accordance with his ideas. If these theories are correct, that the typus humanus attacks only certain parts of the human being and that the typus bovinus attacks other parts, it would be expected that those forms of tubercle said to be due to the bovine type would be uncommon in this country, and such is the case; I have never seen one. I have had a bad case of tuberculous adenitis handed over to me which turned out to be a sarcoma, but I have never got any nearer than that to any of the cases described by Nathan Raw as due to the bovine type of bacillus.

In the annual returns of the Medical Department of the State of Perak the dissimilarity of the figures from those of England is remarkable; in the year 1907, out of 27,178 patients only 37 were recorded as having "other tubercular diseases"—that is, other than pulmonary; and since, as I have said, the only one so diagnosed that I have seen turned out to be sarcoma, perhaps this figure may include other errors of diagnosis or they may have been direct importations from China. The incidence of tubercle in this country practically bears out Nathan Raw's contention. There is no tubercle in animals of any kind, and very little—I think none—of the tuberculous diseases in man ascribed by Nathan Raw to the bovine organism. There is plenty of phthisis; about 10 per cent. of the hospital deaths are from phthisis, and it may be remarked that the disease is apparently increasing. There is plenty of susceptible material, but it gets infected with the human type only, apparently because of the absence of the other.

It is unnecessary here to discuss the antagonism of Koch's and von Behring's views; but if the latter were correct there should be no phthisis in this country, which is unfortunately not the case. Koch's view does not explain the absence of the non-pulmonary forms of the disease. Nathan Raw's explains both. Here we have only personal infection. The converse of this is shown by Dr. Mayo of Rochester, Minn., who says that phthisis pulmonalis is uncommon in that State and that the other forms are common. That is in a grazing country with, I presume, a rural population. Countries like these can be used as controls for the work that is being done in other lands. I send the facts about this country in the hope of adding a little to what is, I believe, the correct view, and because there is much to show that this view is not at all generally accepted; for instance, in the recent discussion on tuberculin dispensaries, now going on in the medical papers, no mention is made of the kind of tuberculin to be used, as though it did not matter. Dr. Bosanquet, in the *British Medical Journal* so recently as Jan 21st, 1911, says, "On the other hand, in pulmonary disease the remedy seems on the whole disappointing," but he makes no mention of the use of a tuberculin from a bovine source; and in a discussion opened by D'Arcy Power and reported in THE LANCET and *British Medical Journal*, "On the Value of New Tuberculin in Surgical Tuberculosis," no mention is made of the idea that these surgical lesions are of bovine origin and that the new tuberculin is made from the bacillus typus humanus.

If these views are correct, the treatment of the disease in temperate climates will be put on to a better plane, while in the tropics the prevention of tubercle is shown to be much more simple than it is in other parts of the world, as it becomes only a matter of personal infection, and so must be dealt with on the lines which are adopted for the prevention of other infectious diseases.

I am, Sir, yours faithfully,

J. TERTIUS CLARKE, M.R.C.S. Eng.,
L.R.C.P. Lond., D.P.H.,
Medical Officer, Lower Perak, F.M.S.

*** This letter forms an interesting commentary on the results of the Royal Commission on Tuberculosis (Animal and Human), to which we refer in a leading article on p. 166. It also emphasises the importance of adequate measures to protect the community against the dangers of tuberculous milk and meat.—ED. L.

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—Perhaps you will kindly allow me space to refer to the amendments suggested by the British Medical Association in reference to representation on the various bodies that will control medical attendance under the State Insurance Bill. The demand made by the Association I regard as quite insufficient.

To the most casual reader of this Bill it must have appeared evident at the first glance that everything is complicated through the overlapping that must necessarily ensue between the Insurance Commissioners and the Local Government Board, and between the Local Health Committees and the existing public health authorities. This may concern us as citizens, but what more particularly concerns us as medical men is that no provision is made for the settlement of disputes that will undoubtedly arise in large numbers between medical men and the insured after the passing of this Bill. To whom are they to be referred? To the Insurance Commissioners? If every petty dispute in every town or village is to be referred to the Insurance Commissioners an enormous department will be required, or, as is more likely, decisions will be hung up and there will be dissatisfaction among all concerned. To the Advisory Committee? This may quite possibly be a temporary body that will disappear after the completion of the Bill. The natural forecast is that unless the Association takes strong action all disputes will be referred to the Local Health Committees. And here it is that the danger lies. If the medical men in a Local Health Committee are, as proposed in the Bill, to be limited to two or even as according to the demands of the Association to one-third or one-fourth of the membership, and the great majority of the committee is to be composed of members of Friendly Societies and representatives of the insured, it is quite evident that when any dispute arises a decision in favour of Friendly Societies and the insured will be a foregone conclusion. For the settlement of these disputes it seems but reasonable that medical men should have the same number of representatives as those providing the funds—namely, the Government and contributories. I readily admit that the appointment of medical committees is a step in the right direction, but it is far from being all that is required.

Perhaps you will allow me to add that the experience of medical men during 30 years of State insurance in Germany has aroused them to the importance of this matter, and in the debates on the new German Bill and in the pages of the journals it has occupied a space only less than that given to freedom of choice. Among medical men in this country the necessity of definite action in this matter has been hitherto entirely ignored, and its importance must be my excuse for again urging the medical profession not to let this Bill pass before some definite action is taken.

I am, Sir, yours faithfully,

Greenwich, July 10th, 1911. J. H. KEAY.

To the Editor of THE LANCET.

SIR,—I note in your article in last week's issue of THE LANCET on this subject that you refer to a proposal of the Chancellor of the Exchequer to add an amendment for contracting out on the part of beneficiaries from the medical benefits and permitting contributions for the same to accumulate to afford a fund to pay a doctor in any future illness to the extent of these accumulations. If such an amendment were accepted it would be an improvement to the Bill as it stands, but it is earnestly to be hoped that the profession will not accept it in the place of an income-limit of £2 a week.

If the profession is pledged to anything it is pledged to decline to accept any appointments under the Bill unless an income-limit of £2 a week is secured by the same. Any surrender of this principle will be fatal to the union of the profession. I am, Sir, yours faithfully,

London, E.C., July 10th, 1911. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—In the leading article in your last issue you state that the Chancellor is considering the introduction of an amendment securing that persons who can pay fees to medical men, although beneficiaries under the Bill, should continue to pay fees.

If in his amendment to Clause 8, Section 7, the Chancellor puts that every beneficiary receiving a total income over £2 a week *cannot claim medical benefits under the Bill and must* do this, then the demand of the medical profession is met. If he will go further and add that the Local Health Committee in conjunction with the Local Medical Committee in any area *may* fix an even *lower* wage limit it would still further please the medical profession, and prevent future local trouble for his scheme.

If, however, the Chancellor omits the first eight words in italics and puts *may* for *must* then the demand is not met. For human nature being as it is, 90 per cent. of these beneficiaries in receipt of an income over £2 a week having had medical benefits conferred on them by Clause 8 of the Bill, will undoubtedly demand such benefits without any further cost to themselves. Mr. Goldman, the Member for Penryn, has put down an amendment that meets the demand of the profession. I am, Sir, yours faithfully,

July 10th, 1911. M.B., B.S.

SALVARSAN ("606") AND MERCURY IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—In the last issue of THE LANCET appears a letter under this heading from the facile pen of Mr. Hugh Wansey Bayly, M.R.C.S., stating that I, amongst others, in criticising the treatment of syphilis by salvarsan "appear to have relied on either very slight experience of the intramuscular method, or on the careful gleanings from the reports of the few opponents and the remarkably small casualty list." I plead guilty to having given my personal experience (a necessarily brief one, as I am not a *protégé* of Professor Ehrlich) of this treatment at a discussion held at the Harveian Society in December last, which discussion was reported in some of the medical journals in a few lines, and on these reports I assume that Mr. Bayly bases his remarks. I can assure Mr. Bayly that I had not the time or the inclination to carefully glean anything from the writings of the few opponents or even from those of the many early friends of this treatment, and why, if I was a hostile critic, I should allude to what Mr. Bayly is pleased to call the remarkably small casualty list passes my understanding. At the discussion alluded to I stated my conviction that salvarsan was a valuable addition to our anti-syphilitic therapeutics, and one which in appropriate cases would enable us rapidly to relieve some of the urgent manifestations of syphilis.

It is a source of deep regret to me that my opinions should not have appeared to coincide with those of Mr. Bayly, pathologist to the Lock Hospitals, to which I happen to be the senior surgeon, the more so as I have been invited to open a discussion at the end of this month on the treatment of syphilis by salvarsan, of which compound Mr. Bayly seems to have constituted himself a champion. The remarkable interest in the treatment of syphilis by salvarsan shown by the pathologist to the Lock Hospitals is a certain augury of its future success in this country, and must be a source of congratulation to the firm of chemists who are retailing this somewhat expensive preparation.

I am, Sir, yours faithfully,

J. ERNEST LANE,
Senior Surgeon to St. Mary's and to the London Lock Hospitals.

July 10th, 1911.

CHLORETONE IN SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—Professor Welsh gives such striking examples in illustration of the efficacy of chloretone in the prevention and cure of sea-sickness that it seems almost an impertinence to cite instances contrary to his. I am emboldened to do so in the hope of helping, even indirectly, to treat this troublesome complaint.

I am a bad sailor, at my best I feel but indifferently well on the sea; as, however, I have often observed other unfortunates succumb sooner and suffer longer, I need not condemn myself to the category of "very bad." My experiences are limited mainly to cross-Channel passages and entirely to voyages of shorter duration than 36 hours. I have tried all the usual preventives, including "specifics" and even the most minute details of preparation and posture;

and during my last two voyages I tried chloretone. Travelling *viâ* Queenborough-Flushing *en route* for Vienna I took 10 grains three times at hourly intervals, the last being swallowed as I embarked. I slept most of the night during a moderate passage, but I woke with such an appalling headache, which together with a feeling of malaise persisted throughout the greater part of the next day, that I held exemption from *mal de mer* dearly purchased at this price. I have never taken hypnotics and cannot say if I have a particular intolerance of them. On my return journey *viâ* Ostend-Dover I adopted the same precautions. The passage was a rough one; after one and a half hours I started to vomit (from previous experiences I would calculate one and a half hours as my usual limit of endurance unassisted by any "anti-sickness specifics"), and I continued to vomit and retch for the next two hours not only as violently as I have ever done, but on this occasion to the usual horrors was added the offensive taste of the chloretone or whatever product of its decomposition was vomited.

I have prescribed chloretone twice to ladies about to undertake crossings. One was spared sea-sickness (there was no certainty that she would have been sick without its administration), but she experienced a headache next morning as I have mentioned in my own case, and she willingly agreed that sea-sickness was a lesser evil. The other patient said that the drug "narcotised" her and that she vomited only during intervals of wakefulness; she complained bitterly of the taste of the vomit.

These few observations upon short sea passages seem very trivial in comparison with those described by Professor Welsh, but they may be the means of drawing some generalisations. I venture to say that sea-sickness is not entirely understood, probably because a number of factors enter into its causation, and it is partly physiological, partly pathological. It is notorious that seasoned travellers who have vanquished the Indian Ocean almost without a qualm are often the worst on board during the short Channel crossing. The conclusion is a tempting one that chloretone is less effectual in Channel sea-sickness because the particular motion in these waters produces a condition which is not affected by chloretone. My explanation of the entire failure of chloretone on the return journey to which I have referred is that the sea passage was after a train journey of 28 hours, for many have observed that fatigue strongly disposes to sea-sickness.

I personally would be only too willing to take any drug administered in any way; but, so far as a short sea journey is concerned, I shall for the future feel more disposed to meet sea-sickness and struggle with it, *quâ* sea-sickness, rather than complicate it with the doubtful advantages I have experienced from chloretone.

I am, Sir, yours faithfully,
ADOLPHE ABRAHAMS, M.B., B.C. Cantab.,
M.R.C.S. Eng., L.R.C.P. Lond.

St. Bartholomew's Hospital, E.C., June 26th, 1911.

To the Editor of THE LANCET.

SIR,—I was very much interested by Professor D. A. Welsh's paper upon the use of chloretone in sea-sickness which appeared in THE LANCET of June 24th. During the first three months of last year, a very stormy season on the North Atlantic, I acted as ship's surgeon on boats running between Scotland and Canada. I tried the effect of chloretone for sea-sickness first upon myself, as previously I had proved a bad sailor, and subsequently upon a few passengers. In my own case I took 5 grains two hours before sailing, 5 grains at the time of sailing, and 10 grains when rough water was encountered, some two hours after sailing. Beyond a slight feeling of nausea at dinner, enough to show that I should have probably been very sea-sick if I had taken nothing, I experienced no discomfort at all, and have since never been troubled by sea-sickness. As my supply of the drug was limited, I could only try its effect upon a few bad cases of *mal de mer*, and in every instance the administration of 15 to 20 grains in 5-grain doses proved sufficient to check the vomiting, and in only one case was there subsequent sickness. On the return journey I was consulted by a young lady at Newfoundland, who had four times previously crossed to Glasgow, and on each occasion had been so sea-sick that she had not been able to take a single meal in the saloon and had landed at the end of the voyage in a weak and prostrated condition. I followed the same treatment in her case as I had in my own, with the result that on the second day out from St. John's she was up on deck feeling quite well, and for the remainder of the passage took all her meals in the saloon. She felt slight nausea an hour after reaching the open sea, and against my advice she took to her cabin and prepared for her usual voyage of misery. Much to her surprise, however, she slept well and did not vomit once.

I am, Sir, yours faithfully,
KENNETH C. G. GRAY, M.B., Ch.B. Glasg.

Glasgow, July 2nd, 1911.

DIET IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—The committee of the National Food Reform Association propose calling at an early date a conference of headmasters of public and private schools, together with members of their staffs, to consider the feeding in such institutions. In coming to this decision the association has been influenced by the very general interest in the subject, of which abundant evidence has lately been forthcoming.

The success of the Conference of Matrons on the Feeding of Nurses in Hospitals, of which a report has been published with a preface by Dr. Robert Hutchison, encourages the hope that a similar exchange of views among those responsible for the health of so important a section of the next generation during the critical years of body-building could not fail to yield valuable results.

In making arrangements for such a meeting, the committee are naturally anxious to act in consultation with the heads of the scholastic profession, from whom, as well as from any others interested, they would be glad to hear.

I am, Sir, yours faithfully,
CHAS. E. HECHT,
Secretary, National Food Reform Association.

178, St. Stephen's House, Westminster, July 5th, 1911.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In your issue of March 11th, 1911, you published an article by me entitled "Infantile Scurvy in a Child Fed on Sterilised Milk." Without any authority whatever, Mellin's Food, Limited, have had that article reprinted, and have been sending it out with their literature as an advertisement. This, I conclude, because Mellin's Food is once mentioned. The advertisement has been sent to me with inquiries by a friend, and has caused me considerable inconvenience. On demanding an explanation from the firm, they wrote me that they "regarded the article as of sufficient importance to merit a wider publicity." I must apologise for troubling you in drawing your attention to the matter, and in conclusion I should be glad if you would let me know if Mellin's, Limited, have any right to act as they have.

I am, Sir, yours faithfully,
FRANCIS BRACHI, M.R.C.S. Eng., L.R.C.P. Lond.

Southsea, Hants.

*** The manufacturers of Mellin's Food should certainly have obtained our correspondent's permission and our own. Our rule in these matters is never to allow republication of any signed article in our columns until the author has satisfied us that he has himself no objection.—ED. L.

LEGISLATION WITH REGARD TO ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Might I be permitted to express opinions somewhat at variance with those contained in your annotation on this subject in your issue of July 8th?

The mere fact that it has taken Sir Frederic Hewitt four years' hard work to bring the matter to its present position is, to my mind, very suggestive. It would almost appear as though there were a lack of enthusiasm in the profession; that the evil which such legislation proposed to correct was not a very crying one; and that the benefit to the public was rather imaginary than real. These at any rate are the views which I (and many others) hold, and have always held, and I venture to think that it is somewhat misleading to state that "there is, practically speaking, unanimity" on the

subject. Sir Frederic Hewitt's recent pronouncements have not, in my opinion, introduced any substantially new facts or arguments in favour of legislation, and I do not, therefore, propose to reiterate the views in opposition which I expressed in your columns and elsewhere in the early part of 1909.

I am, Sir, yours faithfully,

Devonshire-street, W., July 10th, 1911. J. FRED. W. SILK.

THE NECROPSY OF NAPOLEON I.

To the Editor of THE LANCET.

SIR,—The version of the report on the post-mortem examination on Napoleon, which you quote in THE LANCET of July 8th, tallies with a copy of the report preserved in the pathological museum of the University of Aberdeen. Writing without having references at hand, I am unable to say what were the relations between the medical attendants at St. Helena. It may be worth recording, however, that the two foreign doctors did not sign the report as copied; and further, that it is signed not only by Arnott, surgeon, 20th Regiment, but also by Thomas Shortt, M.D., physician and P.M.O.; Charles Mitchell, M.D., Surgeon, H.M.S. *Vigo;* Francis Bruton, M.D., Surgeon, and Matthew Livingston, Surgeon, H E.I.C. Service. Mitchell was M.D. of Marischal College and University, Aberdeen, and his copy of the report was presented by one of his descendants to the surgeon's medical school.

I am, Sir, yours faithfully,

JAMES RAE.

Park Hospital for Children, Hither Green, S.E., July 8th, 1911.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE degree Congregation was held on July 8th. The Right Hon. Sir Joseph Ward, Bart., K.C.B., Premier of New Zealand, was the recipient of an honorary LL.D. degree. Eleven degrees of M.B., B.Ch. were conferred. Henry Percy Pickerill of the University of Otago received the degrees of M.D. and M.D.S. *in absentiâ*. After the degree ceremony a large company of graduates and friends partook of the annual luncheon arranged by the Guild of Graduates. Dr. Stanley Barnes, the President of the Guild, occupied the chair, and among the numerous guests were Sir Joseph and Lady Ward and other colonial visitors. Mr. J. Furneaux Jordan has been appointed to deliver the Ingleby lectures in 1912.

The After-care of Children.

The report of the special schools after-care sub-committee of the Birmingham Education Committee contains a review of ten years' work and emphasises the need of continuous control of the majority of the feeble-minded. It gives a complete account of the present condition of the cases which have been under observation. The report states that, although in this district there is better provision than almost anywhere else, it must once more be insisted that no enterprise or foresight on the part of individual authorities can effectually deal with the problem till the recommendations of the Royal Commission in favour of a single authority and continuous care all over the country are carried out. This would be much more satisfactory than mere promises of legislation. The committee has since its formation dealt with 1174 cases, of which the following is a summary: (1) mentally defective, 763; (2) deaf, 118; (3) cripples, 293; total, 1174. Of the mentally defective 173 are doing remunerative work, 6 work with their parents or other relations at home, 62 are living at home and doing no paid work, 32 were dismissed from special schools as incapable through mental or physical disability, 84 have been transferred to normal schools, 8 have been transferred to schools for the deaf and 1 has been transferred to a school for physically defective children, 43 are in workhouses, 65 in other institutions, 25 are dead, and 210 have been lost sight of. In its general conclusions the committee states that an investigation of statistics shows that out of 425 feeble-minded persons who have left school and are still alive and whose whereabouts are known only 40·7 per cent. are earning wages; only 8·0 per cent. are earning as much as 10*s.* per week; and only 1·4 per cent. 15*s.* per week. The committee repeats its convictions that for the majority permanent control is necessary for the following reasons: (1) to enable them to contribute towards their own support; (2) to save them from harsh treatment at home and in the streets; (3) to prevent their becoming drunkards, criminals, and prostitutes; and (4) to prevent their giving birth to children who must almost certainly grow up to be a burden to the community.

Yardley-road Sanatorium.

Since October last the Emergency Hospital at Yardley-road, which was built for the accommodation of small-pox patients, has been used for the educational treatment of consumptives. A large number of men and women have passed through the institution, and besides the instruction in the methods of open-air treatment all suitable cases have been treated with tuberculin, not only whilst in the sanatorium but afterwards as out-patients. The excellent work carried on by Dr. W. H. Wynn, the visiting physician, and Mr. G. B. Dixon, the resident medical officer, has, unfortunately, been interrupted by a case of small-pox arising in the city. The consumptive patients were sent home and provision was made for the accommodation of this patient and any others that may arise. Since the hospital was built there has been no previous case of small-pox, and when the Greater Birmingham scheme comes into force in November other provision will be made for these cases, and the Yardley-road establishment will be devoted entirely to consumptive cases. Plans are being made to increase greatly the accommodation. It is hoped that the interruption will be of short duration and that no further cases of small-pox will occur.

A Scheme for a Natural History Museum.

A very important scheme has been arranged for a natural history museum for the city. The whole of the third floor on one side of the recent Art Gallery extension will be occupied by it. The committee, of which Professor Gamble is secretary, has formulated proposals for fitting up the rooms. The leading idea is topographical—that is to say, to illustrate the character of the sea, of fresh water, and of land (mountain, moor, desert, meadow, and prairie), and to show the characteristic animals and plants of these divisions of the earth. Side by side with the main idea, which will be extended through two long galleries, there will be a continuous arrangement of specimens, classified in the usual scientific manner, beginning with man and ending with crystals.

July 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Insurance Bill.

AT a meeting of the Scottish Association of Medical Women, held in Edinburgh on July 1st, a discussion took place on the medical aspects of the National Insurance Bill. The discussion was opened by Dr. Annie Mercer Watson, Aberdeen, and the following motion, proposed by Dr. Elsie Inglis and seconded by Dr. Beatrice Russell, was carried unanimously:—

That the six points embodying the policy of the British Medical Association, as contained in the Smith-Whitaker circular of June 3rd, be adopted by this meeting as essential, and that members of this association be urged to join the British Medical Association, and to sign the undertaking to refuse to give medical attendance and treatment to persons insured under this Bill, excepting on such terms as shall be satisfactory to the medical profession, and in accordance with the declared policy of the British Medical Association.

—At a meeting of the medical profession of Caithness held in the Bignold Cottage Hospital, Wick, resolutions were unanimously passed upholding the policy of the British Medical Association regarding the National Insurance Bill. Mr. A. Wilkie, M.P. for Dundee, was interviewed on July 7th by representatives of the Dundee branch of the British Medical Association. The question was raised of the professional status as involved in the relation of doctors to approved societies under the State Insurance Scheme. The Chancellor of the Exchequer having agreed to the principle of free choice of doctors for those insured under the Local Health Committees, they urged that the same principle should be applied to the whole of the medical relief.

Edinburgh University Graduation Ceremonial.

At the summer graduation ceremonial of the University of

Edinburgh, held in the M'Ewan Hall on July 7th, the honorary degree of Doctor of Laws was conferred on H.H. Maharaja Sir Madho Rao Scindia Bahadur, of Gwalior, and among others Thomas Smith Clouston, M.D., late physician-superintendent of the Royal Edinburgh Asylum; James Mackenzie, M.D.; Ernest Rutherford, F.R.S., professor of physics in Manchester; and Sir William Gowers, M.D., F.R.S. On July 8th a special graduation ceremonial was held in the M'Ewan Hall, when honorary degrees were conferred on Sir John Anderson, G.C.M.G., Sir Walter Egerton, K.C.M.G., Sir Everard Im Thurn, C.B., K.C.M.G., Sir Charles A. King-Harman, K.C.M.G., the Right Hon. Sir Edward Patrick Morris, K.C., Sir Sidney Olivier, K.C.M.G., and Sir Alfred Sharpe, C.B., K.C.M.G. After the ceremony the guests were entertained to luncheon in the Students' Union.

Queen Margaret College, Glasgow.

The annual celebration of Founders' Day took place last week at Queen Margaret College. A reception was held in the afternoon and was attended by 400 guests, including Principal Sir Donald MacAlister and Lady MacAlister, members of the Senatus and University Court, and graduates of the College. The visitors were received by the mistress of the College, Miss Melville, M.A., B.D.

The Rectorship of the University of Aberdeen.

Mr. Andrew Carnegie has consented to become a candidate (on non-political grounds) for the Lord Rectorship of the University of Aberdeen.

Aberdeen Parish Council Medical Officers: Attendance at Confinements.

The question as to whether parish council medical officers are obliged by the terms of their appointments to attend paupers at confinements has been under discussion at the Aberdeen parish council. The rule which refers to this matter is as follows: "Every medical officer appointed by the parish council to any such parish or to a district of any such parish shall duly and punctually attend upon, and prescribe for, all poor persons requiring medical or surgical assistance within the parish or district to which he is appointed, whenever he shall be thereunto required by a written or printed order from the parish council or the inspector of the poor; or in cases of sudden or urgent necessity, from a member of the parish council; or by the production, on the part of any poor person, of their pay card." The committee of the council, which had the matter under consideration, resolved that the medical officers were bound to attend to all the poor on the outdoor rolls of the parish when called upon, irrespective of the nature of the ailment.

Small-pox in Paisley.

Last week five cases of small-pox were notified in Paisley. The cause of infection in the first case has not been ascertained, but the other cases were direct contacts. Unfortunately one patient has died in hospital, but the others are doing well, and no new case has occurred for more than a week.

Effects of the New Arts Ordinance on the University of St. Andrews.

The University of St. Andrews closed its summer session (now the third term of the academical year) on June 27th, and the degree examinations have begun. The operation of the new arts ordinance is seen in a substantial increase in the numbers attending the University classes in the summer session both at St. Andrews and at Dundee.

Sanitary Congress at Dundee.

The annual Congress of the Sanitary Inspectors of Scotland was held at Dundee on June 30th. Mr. Thomas Bishop, chief sanitary inspector of Leith, presided. In his opening address he spoke of "Loopholes in Sanitary Law," and said that 14 years ago, when the Public Health Act was passed, farmed-out houses were little known outside of Glasgow, but the system had spread there, and though these houses had not yet found a footing in Dundee, it would be strange indeed if they were not in the near future established there. When once a start was made the number of these houses spread with great rapidity. House factors with property of a certain class saw in this system a way of collecting rents with a minimum of trouble to themselves. The law with regard to the prevention of smoke was much behind the times, and manufacturers ought to be compelled by law to instal modern appliances. The law relating to dairies was antiquated. More control should be given to local authorities, and the premises as well as persons should be licensed. Registration should apply to dealers residing without the jurisdiction of the local authority, but who supply milk wholesale to shops, while cows should with reasonable frequency be examined by a veterinary surgeon. The Food and Drugs Act should be amended to prevent the sale of adulterated food, and also to regulate the manufacture and sale of quack medicines. Mr. Peter Fyfe, chief sanitary inspector, Glasgow, said in speaking on the Destruction or Reconstruction of Slums, that sanitary inspectors in their search for the disease-bearing house and family were met with such an infinite variety of circumstances and such fine shades of differences that they looked in vain for a firm foundation upon which to base their opinion as to whether a given area, small or large, was a slum to be dealt with under Part I. or Part II. of the Housing of the Working Classes Act. Slum reconstruction offered an alternative policy, which was not dependent upon Acts of Parliament, but the keen desire of some housing reformers not unseldom overran their discretion. "Back to the land" was the battle-cry of the garden city enthusiast. The destruction of the city slums, and the erection for the people who inhabited them of delightful cottages in the country or suburbs, on cheap ground was an ideal plan, but a quite Utopian one. In the first place, such people did not want them, and secondly, they could not afford to pay for them. The most successful line of policy was the one which had been to a considerable extent followed by the Glasgow Workmen's Dwellings Company, which was to improve the structure and management of dilapidated slums, let the houses at rents within the reach of the labouring classes, and return 4 or 5 per cent. dividend on the capital expended. Councillor M. Cabe, Dundee, said that in one tenement they would find a man with £2 or £3 a week living in filth and squalor and another man earning 18*s.* a week living in a clean, sweet house. The problem was what to do with the slummer, who in five or six weeks would reduce an up-to-date property to the level of a slum. In the last ten years Dundee town council had compelled property owners to spend £90,000 on improvement, and to-day much of the property was worse than before. Drastic measures must be taken to deal with the slummer. Mr. Thomas Kinnear, chief sanitary inspector, Dundee, said his experience was that if caretakers were appointed in connexion with poor properties there was no difficulty with the tenants. Fifty years ago the greater part of the central area in Dundee was slum property, and could not be otherwise, but there were few properties in the city to-day which he would characterise as slum properties.

July 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Visit to Dublin.

On Monday morning last Her Majesty the Queen honoured the Coombe Lying-in Hospital with a visit. On her arrival she was received by the master, Dr. Michael Gibson, and the matron. Sir John Moore (consulting physician), Dr. F. W. Kidd and Mr. F. T. Heuston (consulting surgeons) were presented to Her Majesty. The Queen visited all the wards of the hospital and conversed with the patients. She took particular interest in a baby born on Coronation Day, and in twins, born on the morning of her visit, who are to be named respectively George and Mary. Her Majesty inspected the new Pembroke Dispensary, which had been opened a few days previously by Her Excellency the Countess of Aberdeen. It is a commodious set of rooms for the examination and treatment of out-patients. Addresses of welcome to Their Majesties were presented by the Royal College of Physicians of Ireland, represented by the President, Dr. J. Hawtrey Benson, and the registrar, Dr. T. P. C. Kirkpatrick, and by the Royal College of Surgeons in Ireland, represented by the President, Mr. R. H. Woods, and the Vice-President, Mr. R. D. Purefoy. On Tuesday afternoon Their Majesties visited Charles-street and opened the new Dispensary for Tuberculosis.

The National Insurance Bill.

Considerable dissatisfaction is felt at the suggestion that the administration of the Insurance Bill in Ireland is likely

to be left in the hands of the Local Government Board for Ireland. That body has never shown much sympathy, it is urged, with the claims of Poor-law medical officers, and it is believed to have blocked the path to reform of the Poor-law on the lines recommended by the Vice-Regal Commission a few years ago. The view is held that if the Insurance Bill is made to apply to Ireland there should be a special body of Insurance Commissioners for Ireland, distinct from any other Government Department. At present there seems to be the greatest uncertainty as to what will be the outcome for Ireland of the Insurance Bill, and this very doubtful state of affairs looks as if some coup were pending. The Bill may be passed, at the Government's suggestion, with the conditions for Ireland, England, and Scotland the same, or special arrangements may be introduced to suit Ireland, or Ireland may be eliminated altogether from the measure. He would indeed be a wise man who would prophesy at the present juncture.

The Queen's University of Belfast.

At the recent summer (June) matriculation 105 candidates entered, of whom 63 passed. Of the successful students, 34 were men and 29 were women. In the Faculty of Medicine 23 out of 35 men passed and 1 out of 2 women; in the Faculty of Arts 18 men entered, of whom 8 passed, and 35 women, of whom 21 passed; while in the Faculty of Science out of 4 men who entered 3 passed, and 7 out of 12 women were successful. Taking the two faculties together—arts and science—there were 28 women who passed and 11 men, while in the Medical Faculty 23 men and 1 woman were successful. The preponderance of women entering in the Faculties of Arts and Science is very remarkable.

The Mater Infirmorum Hospital, Belfast.

As a result of the recent Saturday collection a sum of £976 1*s.* 1*d.* has been realised, which it is expected will be much increased.

Dr. G. Johnstone Stoney, F.R.S.

Many old Queen's University graduates will regret to hear of the death at his London residence, on July 5th, of Dr. G. Johnstone Stoney, a man of the highest scientific attainments, who for so many years—up to the time of its dissolution—was secretary of the old Queen's University of Ireland.

James Anderson Browne, L.R.C.P. & S. Irel.

Among medical men the deepest sympathy is felt with Dr. J. Walton Browne, senior surgeon and chairman of the medical staff of the Royal Victoria Hospital, Belfast, in the death, under particularly sad circumstances, of his only son, Mr. J. Anderson Browne, which occurred suddenly on July 4th in Millbank Military Hospital, London. The deceased, who was just 38 years of age, was a second lieutenant in the Queen's University contingent of the Officers' Training Corps, and in that capacity left for London on the night of Saturday, July 1st, in order to take part with the detachment of his corps in the Royal review at Windsor on the following Monday. He seemed quite well and in good spirits on leaving, but on Sunday he became suddenly unwell and was removed to Millbank Military Hospital, where he passed away on the Tuesday, the cause of death being cardiac disease. A young man of exceptionally kindly nature and of social qualities, Mr. Browne was a great favourite, and his early demise is deeply regretted, both on his own account and because he was his father's son. He was accorded a military funeral in Belfast on July 8th.

July 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Hospital in Paris.

A NEW hospital has been built in Paris to replace the ancient Hôpital de la Pitié, which is to be demolished. The new Pitié is situated on the Boulevard de l'Hôpital, alongside the Salpêtrière. It will contain 998 beds and will comprise 32 medical and surgical buildings. The cost is 11,000,000 francs. Its construction, which was begun in 1905, has been several times interrupted by strikes and more recently by the floods. It is, indeed, a model hospital, as near perfection as possible in regard to the disposition of the wards, the isolation of the pavilions, the heating system, the sterilising plant, the various kinds of laboratories, a radiographic installation, and so forth. It was opened last week, and a part of the beds are already occupied. It is expected that in two months its entire bed capacity will be in use.

Syphilis as an "Industrial Accident."

A singular case has recently been tried before the Tribunal of the Seine. Last year a Parisian dentist's assistant was entrusted by his employer with the adaptation of a dental apparatus to a patient. In the course of the work the assistant wounded his little finger. The patient happened to be a syphilitic, and the assistant thus became infected through the wound. The assistant brought an action, under the law relating to industrial accidents, against his employer, demanding an annuity of 2912 francs. He adduced the moral prejudice inflicted on him by the accident, in that being married and the father of two children, he would henceforth live in fear of infecting the members of his family, and also that from the knowledge that he was now exposed to the remote consequences of syphilis, his physical health and resistance would become diminished. This diminution he estimated at 80 per cent. The Tribunal has just decided that the law concerning industrial accidents is not applicable in his case; for the assistant is engaged in the practice of a liberal profession, and is to be considered as a collaborator of the dentist rather than as a workman or a commercial employé paid to do work distinct from that of his employer. He is not to be regarded as simply a cog in the machinery of a commercial enterprise. In short, the Tribunal has decided that in the liberal professions syphilis cannot be regarded as an industrial accident. This decision has occasioned not a little surprise, for up to now in the hospitals nurses and midwives contracting syphilis in the course of their professional duties have received a pension from the Administration of Public Assistance, which has regarded itself as justly responsible; for the definition of an industrial accident, according to the best legal opinion here, is such an accident as would not logically have occurred if the sufferer had been a free agent, and not one performing a task imposed by his employer.

Arsenical Poisoning among Viticulturists.

The Senate and the Academy of Medicine, on the instigation of M. Cazeneuve, formerly Dean of the Faculty of Medicine at Lyons, a correspondent of the Academy, and a Senator, have again taken under consideration the accidents occurring among vineyard employés from arsenical substances used as insecticides. Since he first took up the subject last year M. Cazeneuve has noted an increase in the number of such accidents, the appearance of a new vineyard pest, the cochylis, having necessitated the use of much greater quantities of sodium arsenate. In the departments of Hérault and of the Ardèche numerous fatal accidents have been observed. The insecticides thus employed are all arsenical, and in some of them the base is arsenate of lead. The poisoning is contracted for the most part when the vine-dresser is using the very primitive insufflators to blow the powder on the leaves of the infested vine. Other accidents, however, happen later to those workmen who handle the vine, in consequence of the absorption of the arsenical dust. Accidents of still another character have ensued in consequence of the peasants keeping stored in their houses for the purposes of viticulture considerable quantities of these arsenical salts, which have been mistaken by their wives and children for foodstuffs, such as salt, soda, or cornflour. These accidents are found only among the vine-workers. The wine from the vines thus treated contains no, or accidentally only negligible, traces of arsenic; but the health of the vineyard workers is seriously menaced, even though it be through their own imprudence. M. Cazeneuve has proposed the appointment of a commission, whose duty it shall be, in the two affected departments, to supervise the use of arsenical preparations, and if necessary, to suppress their use next season. Many members of the Academy of Medicine, M. Gautier, M. Pouchet, M. Chantemesse, and M. Weiss, have strongly supported M. Cazeneuve. M. Bouchardat has even insisted on immediate interdiction; for the vineyard workers, much alarmed by the new invasion of the cochylis, are preparing to enter on a fresh arsenical treatment of their vines just as they are on the point of bearing fruit, and serious fears are entertained that the latter may be rendered toxic thereby.

July 11th

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Grievances of Medical Professors.

A SHORT time ago the titular principals or heads of the Austrian universities and high schools, academical dignitaries whose official title is rector, held a meeting to which also the professors and teachers of these institutions were invited. One of the chief subjects of discussion was the remuneration or so-called honorarium of the professors, both ordinary and extraordinary. Up to a few years ago it was the general custom that a professor received as payment the fees paid by his students, and also certain fees for the examinations, minus a small administrative discount. Under this system each professor felt that his reputation and skill were the real sources of his income, for the students preferred to attend the classes in which they had the best opportunity of learning, and the medical schools in Vienna and Austria generally were flourishing. The Government, however, decided a few years ago to pay the ordinary professors fixed salaries, while the fees of their students were being received by a Government official, but this arrangement was not made applicable to private or special classes or lectures. The result is that the extraordinary professors have for their income only what they can earn by holding special classes, attendance on which is optional and not obligatory on the students. The fixed salaries of the ordinary professors are low, varying between £200 and £400 a year, and a scientific man who has no leisure or no desire to seek private practice in addition to his official work must content himself with this meagre remuneration. It is therefore somewhat difficult to get a medical man of eminence to become a university teacher unless he knows that he will be able to supplement his income by private practice, a course which is not to everybody's taste. The theoretical branches of the medical curriculum, or branches such as experimental pathology and forensic medicine, which are not altogether compatible with private practice, can only be undertaken by teachers possessed of independent means. The above-mentioned meeting of rectors accordingly resolved that the Government should be asked to stop the wholesale appointment of *privat-docenten* and extraordinary professors who have no opportunity for teaching. A professorship ought not to be a mere titular distinction: it is a responsible position for which a competent man is required, and one whose services and time should be paid for.

The Decrease of the Birth-rate in Austria.

In an address recently delivered before the Gesellschaft der Aerzte in Vienna, Dr. Jellner discussed the decrease of the birth-rate and the operation of the various factors which contributed to it. He said that within the last ten years the birth-rate has gone down from 38·2 to 34·1 per 1000 of the population. In the year 1897 statistics showed that 38 women out of every 1000 living and of the child-bearing age had had a child or children, but in the year 1906 the corresponding figure was 36. The decrease of the birth-rate was to some extent compensated for by the decrease of the number of deaths of children during labour, for in 1897 the stillborn children were 1·1 per 1000 births, whereas in 1906 the proportion was only 1 per 1000. The figures would be still better if the excess of births over deaths was considered. In 1897 there were per 1000 of the population 11·8 more births than deaths; in 1906 the corresponding number stood at 12·4. The actual number of births was, nevertheless, decreasing constantly. Several reasons contributed to this result. The industrial population married early and had few children, the agricultural population, although marrying later, had many children, the intentional limitation of the family being evident in the first-mentioned group. The reduction of the birth-rate extended also to illegitimate children; the proportion of whom has gone down from 144 to 123 per 1000 births. On the other hand, the mortality has also gone down, and the progress of science has improved the expectation of life of children. On a general review of the whole subject Dr. Jellner came to the conclusion that the principal factor in the decline of the birth-rate was the intentional prevention of conception or interruption of pregnancy. It occasionally happened that such interference with the natural course of events was quite legitimate from a medical point of view, because it was not always advisable that women suffering from tuberculosis or heart disease or mental derangement should take the risks of childbirth at full term. On the other hand, social considerations might force medical men to reconsider their attitude towards this problem of sexual life. Dr. Jellner said that in families of the poorer classes or where the mother was engaged in some employment which prevented her from giving sufficient attention to a large number of children there was some ground for believing that one or two children, carefully brought up, were better for the community than four or five who must suffer from underfeeding or parental neglect. Many women, however, to whom none of the foregoing conditions applied were found to use either the preventive expedients so widely advertised in the newspapers, or else to interrupt their pregnancy by means of instruments or medicines. He refrained from giving any opinion as to the lawfulness or otherwise of such a procedure, but he emphasised the necessity of improving present legislation on this subject from a social point of view. The extent of the trade in preventive appliances, both in the towns and the country, might be estimated from the fact that one of the firms which supplied the so-called "obturator" for this purpose has sold 8000 of these instruments within two years. Dr. Jellner maintained that this traffic should be prevented by law, and that medical considerations should be paramount in judging when it might be necessary to interfere with the normal course of conception and pregnancy.

July 10th.

Obituary.

ALFRED STILEMAN BOSTOCK, M.R.C.S. ENG., L.S.A.

Mr. Alfred Stileman Bostock, whose death took place at the residence of his son at Leatherhead on July 1st, was born at Horsham in 1846. He became a Member of the Royal College of Surgeons of England in 1867, and a Licentiate of the Society of Apothecaries of London in the following year. He settled at Chichester in 1871 and soon gained a large practice. He took a keen interest in municipal affairs, and in 1884 was elected Mayor of Chichester. He was re-elected to this office in 1891. Early in 1909, owing to failing health, Mr. Bostock relinquished his practice at Chichester and went to Pinnock in Gloucestershire. On leaving Chichester Mr. Bostock received a public presentation "in recognition of the skill, patience, and attention which he has shown, and his great faithfulness and kindness of disposition." He contributed to the *Medical Times and Gazette* in the year 1868 notes upon a case of subclavicular dislocation of the humerus which were made interesting by the fact that reduction was effected after eight years by manipulation.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Franz Kral, professor of bacteriology in the German University of Prague.—Dr. E. v. Hibler, extraordinary professor of pathological anatomy in the University of Innsbruck from septic infection contracted during his demonstrations.—Dr. G. Krönig, *privat-docent* of medicine in Berlin.—Dr. H. Stilling, professor of physiology and pathological anatomy in the University of Lausanne.—Dr. Samuel E. Maynard, professor of gynæcology in the University of Vermont, Burlington.—Dr. Carl Beck, professor of surgery in the New York Post-Graduate School and Hospital.

DONATIONS AND BEQUESTS.—After the disposal of several charitable legacies, particulars of some of which were published in THE LANCET of July 1st, p. 60, the residue of the estate of Miss A. Thorne Harris of Plymouth, which is estimated at about £2100, is to be divided between the South Devon and East Cornwall Hospital, the Didworthy Sanatorium for Consumptives, and the Three Towns Church Extension Fund.—Miss M. Goodenough Cox, of Staplegrove, near Taunton, has bequeathed £3000 to the Taunton and Somerset Hospital.

THE NATIONAL INSURANCE BILL.

OUR readers will have followed in the daily papers the progress which the Bill has made in Committee during the week, while our correspondent in the Lobby of the House summarises in another column the chief points so far as they will affect the position of the medical profession.

On Tuesday evening, in debating the provisions of Clause 8, which details the rates and conditions of medical benefit, some very important speeches were made, especially by the Chancellor of the Exchequer. An amendment was moved to omit the subsection dealing with medical treatment and attendance until the House was in possession of the negotiations at present in progress between the Chancellor of the Exchequer and the medical profession. Mr. Lloyd George submitted that under Clause 14 of the Bill, which deals with the administration of medical benefits, the position of medical men could more conveniently be discussed, but undoubtedly a strong feeling prevailed in the House that it would be necessary to make sure that the terms offered to medical men were such that they would be able and willing to carry on the medical work before proceeding to decide as to the details of that work. The Chancellor pleaded that discussion just now of the medical claims would prejudice pending negotiations, and expressed his anticipation that a satisfactory solution would be reached, adding that the only outstanding question of difficulty was the limit for beneficiaries which should be laid down. Strong representations were made by distinguished Members that the House ought to be allowed to preserve its liberty of action with regard to the clause until after the issue of the pending negotiations, and in the end the Chancellor said that, though in his opinion all the questions could be raised on Clause 14, which would be the fit occasion to discuss whether medical men should attend persons having incomes of more than £2 a week, he would undertake, if he was wrong in this opinion, to recommit the necessary parts of Clause 8 for full debate. The amendment was accordingly withdrawn.

On Wednesday evening the subject of sanatorium benefit was closely debated, when the Chancellor refused to extend the benefit to the wives and children of insured persons. In view of the differences of opinion expressed in the House as to the value of sanatorium treatment we may refer our readers to the important memorandum which appears on p. 180 of this issue of THE LANCET.

The British Medical Association and the Bill.

The British Medical Association has issued to all Members of Parliament a statement of the grounds for the proposals put forward by the Association in connexion with the National Insurance Bill, and we understand that the Council of the Association has decided to open a Central Guarantee Fund of £100,000 to be used for compensation to medical practitioners incurring loss through the operation of the Bill, and to recoup the Association for its expenses in connexion with the Bill.

The memorandum to Members of Parliament, after admitting that in the present state of society interference is to some extent necessary with regard to the relations between the public and the medical profession, states clear preference for the independence of private practice despite its risks to the security of an official service with its restraints. It enumerates the terms of service which were adopted at the mass meeting of the medical profession in the Connaught Rooms on June 1st, which were, it will be remembered, as follows:—

1. An income limit of £2 a week for those entitled to medical benefit. 2. Free choice of doctor by the patient subject only to the consent of the doctor to attend him. 3. Medical and maternity benefits to be administered by Local Health Committees and not by Friendly Societies. 4. The method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the medical profession of the district of that committee. 5. Medical remuneration to be what the profession considers adequate, having due regard to the duties to be performed and other conditions of service. 6. Adequate medical representation among the Insurance Commissioners, in the Central Advisory Committee, and in the Local Health Committees; and statutory recognition of a local Medical Committee representative of the profession in the district of each Health Committee.

As our readers know, certain of these demands of the medical profession have already been met—that is to say, it is understood that one of the Insurance Commissioners will be a medical man, that experienced medical practitioners will find a place on the Advisory Committee, and that each Local Health Committee will contain two medical men. With regard to the fourth and fifth demands, the memorandum points out that the provisions of the Bill can be made to meet the demands of the medical profession if the beneficial arrangements are satisfactory; but with regard to the first, second, and third demands amendments to the Bill are necessary.

Concerning the administration of medical benefits, the memorandum strongly urges that on all grounds such administration should be placed in the hands of the Local Health Committees proposed to be constituted under the Bill. This is, of course, in direct consonance with all that we have written on the matter out of a full knowledge both of the inefficiency of the medical service offered in so many instances by Friendly Societies, and of the relations between those societies and their medical officers.

The memorandum also points out clearly, as we have ourselves, that unless the remunerations and the conditions generally of medical practice are made adequately attractive there will be a serious shortage of medical practitioners in the country. We have already said that the number of students during the last decade having declined steadily, and the standard of the test of qualification having with equal steadiness been raised, unless medical practice offers a reasonable chance of a professional livelihood candidates will be too few.

The question of a wage limit for the time remains in abeyance; presumably the Chancellor's attitude will not be exactly defined until after he has heard the views of the Council of the British Medical Association which meets on July 22nd in Birmingham.

The memorandum of the Association contains the suggestion for mutual agreement to which we alluded last week. It points out that there is general agreement with the view put forward by the medical profession, on the merits of the case, that the section of the community whose income exceeds £2 per week can afford to, and do at present, employ doctors privately to attend them in a very large proportion of cases, and that there is no necessity for insurance or a State subsidy to enable them to obtain ordinary medical attendance. But special surgical skill or institutional treatment may be wanted. If "medical benefit" can be interpreted in such a way that contributions from the Insurance Fund may be made towards the cost of treatment under a private agreement with a practitioner both the profession and the insured may be satisfied. Some such system as we outlined last week, whereby medical benefits may be accumulated against emergencies by compulsorily insured persons who are privately attended, will be required.

The capitation method of remuneration is adopted in the memorandum, but no amount of remuneration is for the present suggested.

The Chancellor's Amendment as to Administration of Medical Benefits.

The Chancellor has put down an amendment to Clause 14 enacting that the Local Health Committees shall make arrangements with practitioners in accordance with regulations made by the Insurance Commissioners, and proposes the following provisions:—

The regulations made by the Insurance Commissioners shall provide for the arrangements being made subject to the approval of the Insurance Commissioners and being such as to secure that insured persons shall receive adequate medical attendance and treatment from the medical practitioners with whom arrangements are so made, and shall require the adoption by every Local Health Committee of such system as will secure:—

(*a*) The preparation and publication of lists of medical practitioners who have agreed to attend and treat insured persons whose medical benefit is administered by the committee and resident within the area to which the list relates;

(*b*) A right on the part of any duly qualified medical practitioner who is desirous of being included in any such list as aforesaid of being so included, except in cases where the Insurance Commissioners, after inquiry, are satisfied that his inclusion or continuance in the list would be prejudicial to the efficiency of the medical service of the insured;

(*c*) A right on the part of any insured person of selecting from the appropriate list the practitioner by whom he wishes to be attended and treated and, subject to the consent of the practitioner so selected, of being attended and treated by him;

(*d*) The distribution amongst the several practitioners whose names are on the lists of the insured persons who after due notice

have failed to make any selection, or who have been refused by the practitioner whom they have selected:

Provided that if the Insurance Commissioners are satisfied that the practitioners included in any list are not such as to secure an adequate medical service in any area, they may dispense with the necessity of the adoption of such system as aforesaid as respects that area and authorise the committee to make such other arrangements as the Commissioners may approve.

Pharmaceutical Interests and the Bill.

No event has occurred in our time which has had the effect of uniting chemists and druggists so firmly as the introduction of the National Insurance Bill. The mass meeting held at the Holborn Restaurant on July 6th was at least twice as large as any gathering of pharmacists that has ever assembled in this country and ten times bigger than the historic meeting held at the Crown and Anchor Tavern in the Strand 70 years ago, at which it was resolved to form an association, under the title of the Pharmaceutical Society, "for the purpose of protecting the permanent interests and increasing the respectability of chemists and druggists." The number of pharmacists at last week's meeting was little short of a thousand, some of whom had come from as far north as Aberdeen, while practically all the large towns in Great Britain were represented; there was also a fair sprinkling of women pharmacists. The object of the meeting was to consider the form of proposed amendments of the National Insurance Bill, and with only four or five dissentients the large gathering expressed approval of amendments embodying the principles formulated by the Council of the Pharmaceutical Society. In many instances these amendments are in the same terms as amendments which have been drawn up on behalf of the medical profession, as, for instance, those which provide that Local Health Committees and not Friendly Societies shall control the medical and pharmaceutical services under the proposed scheme. Mr. Lloyd George has intimated to pharmaceutical representatives that he regards this proposal favourably, and although the amendments may not be adopted by the Government Ministerialists will be free to vote for them. Their fate, therefore, depends upon the impending fight in the House of Commons between the Friendly Societies and the united forces of the medical profession and pharmacists. The efforts which pharmacists are making, individually and collectively, to induce Members of Parliament to support these amendments should materially assist medical practitioners in their campaign. Just as medical men are desirous that insured persons should have a "free choice of doctor," so pharmacists desire that insured persons should be allowed a "free choice of chemist," and one of the amendments of Clause 14 of which the meeting approved proposes that Local Health Committees shall prepare lists of "persons, firms, and corporate bodies ..... lawfully entitled to carry on the business of a pharmaceutical chemist or chemist and druggist"; that the lists shall include all those who apply to be included, provided their appointment would not be prejudicial to the efficiency of the service; and that every insured person shall be entitled to make a free selection from the local list. As to the method of remuneration, the meeting approved of an amendment providing that payment should be made in accordance with a scale of charges to be agreed upon between the Local Health Committee and those carrying on business as chemists within the area of the committee, and, failing such an agreement, upon a scale of charges to be fixed by the Insurance Commissioners. It is also proposed to add a new clause to the Bill, providing for the formation of local pharmaceutical committees to advise the Health Committees on all matters affecting arrangements for the supply of drugs, the clause being in similar terms to that which is to be moved on behalf of the medical profession. The object of other amendments is to prevent Friendly Societies from establishing dispensaries and to secure that the dispensing of medicines and the supply of drugs under the proposed scheme shall be in the hands of qualified persons. It will be remembered that it was pointed out in these columns[1] that there was nothing in the Bill which would prevent societies from making arrangements for the dispensing of medicines by unqualified persons, who need not be under the supervision of registered medical practitioners and pharmacists, and that subsequently, on the General Medical Council drawing the attention of the Chancellor to this defect, he promised to amend it. It is, therefore, understood that the Government will support the amendment embodying the principle that the supply of drugs shall be in the hands of properly qualified persons. With regard to the position of those dispensers holding the certificate of the Society of Apothecaries, who at present are engaged as dispensers to medical practitioners, many of them will be thrown out of employment if the proposed scheme comes into operation whereby medical practitioners will not provide medicines for insured persons. But the transference to chemists' shops of a considerable amount of work that is now done through medical practitioners will necessarily require pharmacists to obtain further assistance, and there would appear to be no reason why those who have been acting as dispensers to medical practitioners should not be employed in chemists' shops, but their work will be done under the supervision of registered pharmacists.

[1] THE LANCET, May 20th, 1911, p. 1362.

The London Provident Dispensaries and the Bill.

The London Provident Dispensaries Council, representing upwards of 40 provident dispensaries in London, met recently, under the chairmanship of the Duke of Devonshire, to consider the National Insurance Bill in its relation to the work of provident institutions. The following resolutions were unanimously adopted:—

1. That in the interests of more than 110,000 members of the working classes, earning not more than £2 a week, and contributing for their own medical treatment, it is most desirable that the provident dispensaries of London, which are approved by the medical profession, and many of which have existed for more than 50 years, should be utilised for the administration of the medical benefits under the National Insurance Scheme.
2. The appointments on the medical staff of provident dispensaries should be open, as now, to all general practitioners, and that each insured person or subscribing member should have a free choice of doctor from that staff.
3. That, in accordance with the customary regulations, only those persons whose total income is not more than £104 a year should be eligible for medical benefits in the dispensaries.
4. That the attention of the Chancellor of the Exchequer should be specially drawn to the great value of provident dispensaries as providing adequate medical relief on provident lines for women and children as well as for men.

These resolutions are supported by 22 of the principal country provident dispensaries with a membership of more than 174,000 persons. It is hoped that a deputation representative of the provident dispensary movement generally will have an early opportunity of bringing the resolutions before the Chancellor of the Exchequer.

The London County Council and the Bill.

The London County Council on July 11th adjourned to a special meeting on Monday next the consideration of the reports of various committees upon the effect of the National Insurance Bill from a local government point of view, summarised in THE LANCET last week, p. 112. The Education Committee meanwhile has reported in detail upon the Bill in relation to school medical work, urging incidentally that to avoid overlapping with the educational work of the Council the duties of the new Local Health Committees of "organising instruction in the principles of public health" should be of an advisory character only. The Committee also raised the consideration that if the employers' contribution in respect of persons under 18 years of age be less than for adults a premium would be placed on the employment of juvenile labour.

Mr. M. A. Curry desires through our columns to tender his gratitude to the colleagues who gave him their votes at the recent election for the position of Direct Representative on the General Medical Council.

DUNDEE INSTITUTION FOR THE BLIND.—At the annual meeting of the supporters of this institution the chairman, in moving the adoption of the reports, made reference to the munificence and untiring attention given to the institution by Mr. and Mrs. Molison, and afterwards by Sir William and Lady Ogilvy Dalgleish. These two families had given over £20,000 to the institution. Reference was made in the reports to the increased allowance to the poorer paid inmates. It was well known that not only in Dundee, but throughout the country, many people were interesting themselves in an attempt to get State assistance of some kind towards these greatly afflicted classes, and he trusted that something would be evolved which would deal generously with the blind and not unjustly with other people. The reports were unanimously approved.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology, held on June 29th, 30th, and July 3rd and 5th, 76 candidates presented themselves, of whom 43 passed and 33 were referred. The following are the names of the successful candidates:—

Hallowes Lloyd Addison, King's College; Irene Bastow, Royal Free Hospital; George Arthur Batchelor, St. Mary's Hospital; William Arthur Hazlerigg Noel Bell, St. Thomas's Hospital; Guy Kenneth Butterworth, St. Mary's Hospital; Paulin Roger Chevreau, Guy's Hospital; Francis Howard Cleveland, St. Bartholomew's Hospital; John Duncan Legge Currie, Cambridge University and St. Bartholomew's Hospital; Henry Speldewinde de Boer, Ceylon Medical College and Middlesex Hospital; Cassidy de Wet Gibb, Guy's Hospital; Stanley Willoughby Green, Leeds University; Owen Hairsine, Middlesex Hospital; Mostafa Hammouda, Cairo and London Hospital; Arthur Geoffrey Patteson Hardwick, London Hospital; William Clavering Hartgill, London Hospital; Henry Sydney Colchester Hooper, London Hospital; Alfred Morgan Hughes, Westminster Hospital and King's College; Manishanker K. Joshi, Bombay University and Middlesex Hospital; Sydney Hudson Keys, Middlesex Hospital; Mahomed Moosa Khan, Bombay University and London Hospital; Joseph Kinnear, St Thomas's Hospital; Allan Osborne Knight, Middlesex Hospital; Robert Ancel Leembruggen, Ceylon Medical College and Middlesex Hospital; Cecil Granville McClymont, Guy's Hospital; Kenneth Holl McMillan, St. Thomas's Hospital; William Fidler Mason, Leeds University; Walter Edgar Masters, London Hospital; Henry Marie Alphonse Menagé, St. Bartholomew's Hospital; Edward Hugh Morris, Charing Cross Hospital; Duncan Westlake Pailthorpe, Charing Cross Hospital; Lily Fanny Pain, Royal Free Hospital; Arthur Bennet Preston, London Hospital; Ibrahim Rashad, Cairo and St. Thomas's Hospital; Pierre Joseph François Louis Rathier du Vergé, Guy's Hospital; Clive Watney Roe, Charing Cross Hospital; John Patrick Shaw, Middlesex Hospital; Thomas William Sheldon, Cambridge University and Guy's Hospital; Gavin Stiell, St. Thomas's Hospital; Aly Heidar Taymour, Cairo and Guy's Hospital; George O'Neill Waddington, London Hospital; Rupert Edward Shawe Waddington, Middlesex and St. Bartholomew's Hospitals; Thomas Mansergh Wood-Robinson, Middlesex Hospital; and Frank Hamersley Woods, St. Bartholomew's Hospital.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degrees held in Easter term the following candidates were successful:—

FIRST EXAMINATION.

Part I., Chemistry.—C. G. Ainsworth, B.A., Downing; S. L. Bhatia, Peterhouse; J. C. Bramwell, B.A., Trinity; J. S. Eloff, Trinity Hall; F. G. Lewtas, Caius; C. R. Mackenzie, Trinity; and A. G. P. Wills, Corpus Christi.

Part II., Physics.—C. G. Ainsworth, B.A., Downing; S. L. Bhatia, Peterhouse; J. C. Bramwell, B.A., Trinity; and J. M. Howlett, B.A., Downing.

Part III., Elementary Biology.—J. T. Bleasdell, H. Selwyn; J. R. Earp, St. John's; J. S. Eloff, Trinity Hall; C. Gardiner-Hill, Pembroke; J. R. Harris, Queens'; and W. D. Newcomb, Trinity.

SECOND EXAMINATION.

Part I., Human Anatomy and Physiology.—A. C. Ainsley, Caius; S. G. Askey, B.A., St. John's; M. L. Atkinson, B.A., Emmanuel; K. B. Bellwood, Pembroke; H. J. Bower, B.A., Emmanuel; I. M. Brown, B.A., Downing; B. Burnside, Clare; H. A. Crouch and E. V. de Souza, B.A., Downing; E. Donaldson, B.A., Trinity; B. J. L. Fayle, Emmanuel; C. H. M. Gimlette, Caius; C. H. Gow, Emmanuel; B. Graves, B.A., Christ's; N. Gray, B.A., Emmanuel; L. M. Ingle, King's; R. W. P. Jackson, Clare; B. B. Jareja, Trinity; A. S. L. Malcolm, Caius; J. B. Matthews, Clare; G. C. Metcalfe, Caius; S. H. Miles, Clare; S. C. Miskin, Emmanuel; A. V. O'Keefe, Sidney Sussex; C. F. Pedley, B.A., Jesus; J. R. Rees, King's; E. C. W. Starling, B.A., Jesus; W. G. Thompson, Downing; L. H. D. Thornton, B.A., Emmanuel; G. S. Trower, King's; R. L. M. Wallis, B.A., Downing; T. Warrington, Emmanuel; G. C. Wells-Cole, Caius; and F. B. Winfield, Downing.

Part II., Pharmacology and Pathology.—H. A. Bell, B.A., Jesus; B. K. T. Collins, B.A., H. P. Dawson, B.A., and H. V. Deakin, B.A., Trinity; H. Hartridge, B.A., King's; T. J. H. Hoskin, B.A., and H. A. Lucas, B.A., Trinity; R. K. Merson, B.A., Emmanuel; H. A. Richards, B.A., Clare; C. J. Scholtz, B.A., Emmanuel; J. E. Sharp, B.A., Caius; A. G. G. Thompson, Pembroke; and H. A. Williams, B.A., and H. G. Wiltshire, Emmanuel.

THIRD EXAMINATION.

Part I., Pharmacology and General Pathology.—D. S. Bryan Brown, B.A., Downing; E. Calvert, B.A., and C. G. H. Campbell, B.A., St. John's; G. W. B. Garrett, B.A., and B. Haigh, B.A., Caius; R. Heaton, B.A., Christ's; J. M. Jarvie, B.A., Emmanuel; R. H. Mawhood, B.A., Trinity; H. M. B. Nicoll, B.A., Caius; M. J. Petty, B.A., Downing; N. P. Pritchard, M.A., Trinity; A. H. Richardson, B.A., St. John's; R. M. Soames, B.A., Trinity; G. W. Spencer, B.A., St. John's; H. M. Stephenson, B.A., Caius; P. Verdon, B.A., and H. Walker, B.A., Jesus; and S. Wood, B.A., Christ's.

Part II., Surgery, Midwifery, and Medicine.—The following have now satisfied the examiners in all three sections: R. L. Barker, B.A., Caius; A. W. Bourne, B.A., Downing; H. Bowring, B.A., King's; R. D. D. D. Brownson, B.A., St. John's; H. G. P. Castellain, M.A., Trinity; H. J. M. Cursetjee, Caius; F. C. Davies, B.A., Downing; K. J. A. Davis, B.A., King's; H. T. Depree, B.A., Clare; S. Dixon, M.A., Trinity; G. H. Dunn, M.A., Pembroke; C. Ede, B.A., and R. Gamlin, M.A., King's; E. St. G. Goodwin, M.A., J. P. Hill, B.A., and G. Hoffmann, B.A., Caius; J. C. John, B.A., King's; A. C. Johnson, B.A., Downing; R. J. B. Leney, B.A., and D. N. McLeod, B.A., Caius; W. G. Marsden, B.A., Emmanuel; O. de B. Marsh, B.A., Pembroke; R. M. Miller, B.A., Clare; A. H. Moore, B.A., Trinity; A. F. Morcom, B.A., Clare; H. M. B. Nicoll, B.A., and P. A. Opie, B.A., Caius; B. A. Playne, B.A., Pembroke; J. B. Pulling, B.A., Christ's; A. H. Richardson, B.A., St. John's; F. H. Robinson, B.A., Queens'; A. Sandison, B.A., Trinity; W. Shipton, B.A., Emmanuel; C. Strickland, M.A., and F. H. Watson, B.A., Caius; V. T. P. Webster, B.A., Emmanuel; and V. J. Woolley, M.A., King's.

UNIVERSITY OF BIRMINGHAM: FACULTY OF MEDICINE.—The following is the list of successful candidates at examinations held in June:—

I. *Degree of Doctor of Medicine.*—Henry Percy Pickerill.

II. *Degrees of Bachelor of Medicine and Bachelor of Surgery.*—Class II.: Evan Davies, John Selwyn Edwards, Oscar Madeley Holden, Elizabeth Stephens Impey, Charles Crawford Jones, Ronald Douglas Nelson, and Charles Ernest Salt.

III. *Fourth Examination for the Degrees of M.B., Ch.B. (Forensic Medicine, Toxicology, Public Health, and Therapeutics).*—Class II.: George Herbert Alabaster, Ralph Alexander Broderick, Eric Francis Buckler, George Ernest Elkington, David John Evans, Travis Hampson, Elsie Mary Humpherson, John Christopher Jones, John Burman Lowe, Horace Clarence Nickson, Percival Thomas Priestley, Herbert Sheasby, Charles Lovell Spackman, Ronald Joseph Tennant Thornhill, and Alan Ayscough Wilkinson.

IV. *Third Examination for the Degrees of M.B., Ch.B. (Pathology and Bacteriology and Materia Medica and Pharmacy).*—Class II.: Elsie Mary Humpherson. Passed in part of the Examination: James Henry Ritchie (Pathology and Bacteriology). Completed the Examination: David John Evans.

V. *Second Examination for the Degrees of M.B., Ch.B. (Anatomy and Physiology).*—Class II.: John Clifford Brown, John Edward Foley, Henry Gauntlett Langdale-Smith, Arthur David Millington, Kenneth Bernard Pinson, Cyril Alban Raison, Leslie Douglas Roberts, Alfred Percy Smith, Cecil George Teall, Bernard Wood-White, and Montague Sydney Woolf.

VI. *First Examination for the Degrees of M.B., Ch.B. (Physics, Chemistry, and Biology).*—Class II.: John Henry Crosskey, Lillie Mary Donovan, Alice Muriel Evans, George Cecil Mathie, Raymond Fearle Pinson, Hilda Nora Shufflebotham, and Arthur Peregrine Thomson. External candidates: Frank Newey and Baron Theodore Rose. Passed in part of the Examination: Francis Charles Lees (Chemistry and Biology) and Mabel Eliza Prosser (Chemistry and Biology). Completed the Examination: Eric Shirley Jones.

VII. *Degree of Master of Dental Surgery.*—Henry Percy Pickerill.

VIII. *Degree of Bachelor of Dental Surgery.*—Class 1: Humphrey Francis Humphreys.

IX. *Third Examination for the Diploma in Dental Surgery (Anatomy and Physiology and Dental Anatomy and Dental Histology).*—Arthur Bernstein and John Jessop. Completed the Examination: Edgar George Jones.

Russell Memorial Prize in Nervous Diseases.—Oscar Madeley Holden.

VICTORIA UNIVERSITY OF MANCHESTER.—The following candidates have been approved for the degree of M.D.:—

*H. E. Allanson, W. E. Bamber, G. H. Brown, H. H. Bywater, J. F. Corson, *J. R. Hutchinson, G. H. Leigh, *Peter Moran, †R. H. Titcombe, *Herbert Tomlin, H. G. Ward, *Henry Whitehead, *B. M. Wilson, James Wood, M. S. Wood, A. E. Woodall, and *J. S. Young.

* Commendation. † Awarded gold medal.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Julius v. Michel, Director of the Ophthalmic Clinic in the Ziegelstrasse, will retire at the close of the current session.—*Gratz:* Dr. Fritz Hartmann, Extraordinary Professor of Psychiatry and Neurology, has been promoted to the Ordinary Professorship.—*Halle:* Dr. Hans Kathe has been recognised as *privat-docent* of Hygiene.—*Kiel:* Dr. A. Böhme has been recognised as *privat-docent* of Medicine.—*Königsberg:* Dr. Klieneberger, *privat-docent* of Medicine, has been granted the title of Professor.—*Lemberg:* Dr. R. Renckci, *privat-docent* of Medicine, and Dr. M. Herman, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships.—*Naples:* Dr. Alfredo Perrone has been recognised as *privat docent* of External Pathology and Dr. Francesco Visco as *privat-docent* of Pædiatry.—*Prague (German University):* Dr. F. Hofmann of Innsbruck has been appointed to the chair of Physiology in succession to Dr. Gad.—*Rome:* Dr. Giuseppe Franchini has been recognised as *privat-docent* of Internal Pathology.—*Rostock:* Dr. Unterberger has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Siena:* Dr. Metello Francini has been recognised as *privat-docent* of Surgery and Operative Medicine.—*Upsala:* Dr. Gunnar Forssner of Stockholm has been appointed Professor of Pædiatry and of Medicine.—*Vienna:* Dr. Norbert Ortner of Innsbruck has been appointed to the chair of Clinical Medicine in succession to Dr. von Strümpell. Dr. Clemens v. Pirquet of Breslau has been appointed to the chair of Pædiatry in succession to the late Dr. Escherich.

UNIVERSITY OF LEEDS.—At a Congregation of the University held on July 1st, the degree of Doctor of Medicine was conferred on Mr. Harold Vallow.

The Worthing education committee has received a letter from the secretary of the Worthing Hospital intimating that until the effect on the hospital of the proposed Insurance Bill has been ascertained, it is not proposed to make any arrangements for the X ray treatment of children suffering with ringworm.

Dr. J. E. M. Finch, medical superintendent of the Leicester Borough Lunatic Asylum, has indicated his intention to resign from that post this year. In September Dr. Finch will complete 42 years of service. He was appointed medical superintendent when the asylum was built in 1869. It then had accommodation for 300 patients; additions and enlargements since have brought up its capacity to 856.

ABERCHIRDER COTTAGE HOSPITAL.—The annual meeting of the trustees of the Rose-Innes Hospital, Aberchirder, took place on June 30th. The balance sheet for the year was submitted, and showed an income of £191 5*s.* 11*d.* and an expenditure of £184 2*s.* 10½*d.*, leaving a balance of £7 3*s.* 0½*d.*; and also showing a bank balance of £62 and an endowment fund of £3860 11*s.* 4*d.*

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—The annual meeting and banquet of this association will be held at the Garden Club, Coronation Exhibition, on Saturday, July 22nd, at 7.30. All graduates of the University of Brussels are welcome, and members are invited to bring ladies. Tickets, price 7*s.* 6*d.* (not including wine), may be obtained from the honorary secretary, Dr. Arthur Haydon, 23, Henrietta-street, Cavendish-square, London, W.

ASSOCIATION FOR THE ORAL INSTRUCTION OF THE DEAF AND DUMB (11, FITZROY-SQUARE, W.).—At the Portman Rooms, Baker-street, W., on Monday next, July 17th, at 3.30 P.M., the annual meeting of this association will be held, and a short illustration of the system given. The Right Hon. Sir John Gorst is announced to preside. All medical men will be welcome. The admirable educational work done by this association is too little appreciated by the public.

WOMEN'S IMPERIAL HEALTH ASSOCIATION.—A *fête* and two days congress were held last week under the auspices of this association. The object of the association is to disseminate the elementary principles of hygiene among the general public through the women of the Empire, instructing them in the care and nurture of children, the values of food and cookery, the prevention of disease by simple knowledge of sanitation, and so forth. Lectures and educational meetings are held in London and the provinces, lantern slides and cinematograph pictures are shown, and two caravans, one staffed by medical men and the other by nurses, travel through the country holding health meetings and demonstrations in all the towns and villages they pass through. The Duke of Argyle (in the absence of H.R.H. Princess Louise) opened the *fête* in the Botanic Gardens, London, on July 5th, when one of the caravans was open to inspection. The congress was held at the Caxton Hall, Westminster, on July 6th and 7th, and the subjects dealt with included "Tropical Diseases as they Affect Women and Children" (Dr. C. W. Daniels), "The Prevention of Plague" (Dr. F. M. Sandwith), "The Endowment of Maternity and its Relation to Eugenics" (Dr. R. Murray Leslie), and "The Tuberculosis Problem" (Dr. Marion B. Andrews). An interesting memorandum on some of the medical organisations at work in India for the relief of women, by Surgeon-Lieutenant-Colonel Sir Warren Crooke-Lawless, C.I.E., was read. It revealed the rapid and extraordinary development of the association commonly known as the Countess of Dufferin's Fund, founded in 1885 for the provision of female medical practitioners for the native women, who were not allowed to see or consult doctors of the opposite sex. It also established a system of scholarships to help Indian ladies to become duly qualified practitioners, and the scheme met with the cordial support of all India. Another association which has steadily increased and is doing excellent work is the Victoria Memorial Scholarship Fund, established by the late Lady Curzon to improve the conditions of childbirth in India. Speaking of the more serious effect of tropical climate upon women than upon men, Dr. Daniels maintained that it was due to the lack of outdoor occupations and interests among women who, leading idle lives, lost ability to resist the enervating influence of the climate. Dr. Sandwith insisted on the necessity for keeping watercourses absolutely clear of all weeds and other growths in order to prevent the spread of plague through mosquito beds, and gave some interesting facts concerning rats and the fleas which have been proved a great source of infection. The discussion on the Endowment of Maternity might be described more as having a political and social economy bearing than as a strictly medical or "health" subject, but it brought out the co-responsibility of the father in all maternal relations with the child. The possibility of State endowment interfering with such responsibility was also referred to. The discussion emphasised the opinion that, in spite of the falling birth-rate, our population and the population of America are maintained by the marked decrease in the death-rate, owing, as Dr. Woods Hutchinson believed, to the improved health and fitness of the mothers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill in Committee.

THE House of Commons commenced the consideration of the National Insurance Bill in committee on Wednesday, July 5th. The Chancellor of the Exchequer is in charge of the measure, but he is receiving the assistance of several other Ministers in conducting it through the House. The Bill contains 87 clauses, 59 of which have relation to National Health Insurance. The administration of medical benefit is dealt with in Clause 14, and it is on it that the demands of the medical profession for fairer treatment will be raised in their acutest form. However, matters of the very closest concern to the profession arise on other clauses. The second part of the Bill deals with unemployment insurance.

On Wednesday, July 5th, a motion was made to enable the Committee to divide the Bill into two Bills, but this proposal was defeated by 254 votes to 165. In the course of the discussion on this motion Mr. LLOYD GEORGE made two important statements. He said, in the first place, that subject to the limitation that the commitments of the Exchequer should not be increased he should not regard any change which the House would think fit to make in the Bill either as a defeat of the Government or as a defeat inflicted on himself. If there were any suggestions from any part of the House which commended themselves to the House as a whole as better than the suggestions of the Government, by all means it was the duty of the House to carry those suggestions through. His second important statement had reference to the demands of the medical profession. "After all," he said, "the criticism which has most body in it as far as one can judge from what has appeared in the press in that of the doctors. The criticism of the doctors has had far more attention given to it in the press than any other criticism which has been directed to the Bill. Substantially I think the honourable Member (Mr. LANSBURY) will find that they are reconciled to the proposal which the Government has made." In the course of the day's debate Mr. LLOYD GEORGE let again fall a similar remark in regard to meeting the opposition of the medical profession.

Clause I. of the Bill concerns insured persons. An amendment to include in the scope of the Bill the wives of insured persons was rejected. A proposal to include in the category of insured persons all the members of five years' standing of friendly societies becoming approved societies was opposed by Mr. LLOYD GEORGE on the ground that it would admit well-to-do persons to the benefits of the Bill. He pointed out that this would really entail a further inroad on the private patients of medical men. This proposal was defeated by a large majority.

Towards the end of Wednesday's debate Mr. JOYNSON-HICKS brought forward an amendment to exclude from the voluntary contributors persons whose income amounted to £160 a year and upwards. In accepting the amendment, Mr. LLOYD GEORGE said that its adoption would simplify matters so far as the medical profession was concerned. One of the greatest difficulties which the Government had had was the apprehension under which medical men were labouring that the class of patients which enabled them to give more liberal treatment to the lower wage-earning community would be taken from them and that they would have in future to deal with them on contract terms. Therefore, the Chancellor added, he could not resist an amendment of this kind. He agreed that a great scheme of national insurance of this kind should provide medical and maintenance benefits for those who are unable to provide them for themselves, and he thought that those who

were over the income-tax limit hardly came within that category. The amendment was adopted. Clause I. as amended was agreed to before the House rose on Wednesday night.

On Thursday, July 6th, the House of Commons considered the second clause of the National Insurance Bill, which dealt with exemptions to the categories of insured persons. On it the Chancellor of the Exchequer intimated that he had directed his actuaries to prepare statistics which would enable him to deal in a special class with hospital nurses, who as part of their contract service already enjoyed free medical treatment and care during sickness, but not disablement benefit. Later in the evening, in committee of ways and means, a resolution was passed authorising the payment of sums necessary for carrying out the purposes of the Bill out of moneys provided by Parliament. Sir HENRY CRAIK strongly criticised the provisions of Clause 14, which throws upon county councils the burden of making up the excess expenditure on medical benefit to the extent of one-half in cases where it "is reasonable and proper in the circumstances."

These points of financial adjustment were again discussed on Friday, July 7th, on the report of the money resolution. Various points dealing with the Post Office contributors and the sanatorium benefit were raised in the course of the debate. Sir PHILIP MAGNUS expressed the opinion that the House should be informed of the communications which had taken place between Mr. LLOYD GEORGE and the medical profession. Dr. ESMONDE later in the debate expressed the opinion that it was rather unfair to ask the Chancellor to give the House the facts that led him to make a statement in connexion with the settlement with the medical profession. It was perfectly well known that there had been deputations to the Chancellor of the Exchequer and interchange of views, and it was also well known by those who were studying this question that no arrangements could possibly be made between the medical profession and the Chancellor until such time as they were submitted on July 21st to a representative medical meeting. Therefore Dr. ESMONDE thought that it was hardly fair to press the right honourable gentleman at this stage to make any further statement with reference to that question. Mr. LLOYD GEORGE, in his reply, did not enlighten the House as to the nature of his negotiations with the medical profession. He alluded, however, at some length to the sanatorium part of his scheme as an experiment well worth making, but most of his points on it are familiar now to those who have followed his utterances on the Bill. The report of the financial resolution was agreed to.

On Tuesday evening when the House of Commons came to the consideration of Clause 8 (Rights and Conditions of Benefits) an attempt was made to induce the Chancellor of the Exchequer to give a statement of the position of his negotiations with the medical profession. Clause 8 provided that one of the benefits which insured persons were to receive was medical benefit, and Mr. JOYNSON-HICKS moved as an amendment the deletion of this provision on the ground that the House ought to have the pending negotiations explained before it dealt with medical benefit. Mr. LLOYD GEORGE at once replied that the proper place to discuss the arrangements with the medical profession was on Clause 14. He said that it was through no fault of his that he was not in a position to inform the House as to the exact situation, but certain proposals were before the medical profession. Debate in Parliament would undoubtedly prejudice the discussions now going on. When Clause 14 was reached, he was sanguine that an arrangement would have been arrived at satisfactory to the medical profession and to those who wished to see medical treatment given under the best conditions. He asked Mr. JOYNSON-HICKS not to press his amendment, as it would make the discussions with the medical profession very difficult. He must at the present stage decline to enter into full particulars on this matter until he heard the views of the medical profession on the proposals before them. Otherwise there would be "an infinity of harm."

Some discussion took place as to the necessity of securing to the House full opportunity to deal with the effect of the Bill on the medical profession after a disclosure of the negotiations had been made. Sir ROBERT FINLAY expressed the view that it was essential, before the House committed itself to the inclusion of medical benefits, that honourable Members should know in general terms what the attitude of the Chancellor of the Exchequer to the medical profession was going to be. Dr. ADDISON said that he was quite confident that any detailed discussion of the position of the medical profession at this stage would be thoroughly mischievous. Sir PHILIP MAGNUS took a similar line to that followed by Sir ROBERT FINLAY. Sir HENRY CRAIK, who spoke as the representative of 5000 medical graduates, asked for assurances for an adequate discussion subsequently of the points concerning the medical profession. Mr. LLOYD GEORGE still kept to his view that these quetions were appropriate only to Clause 14. He mentioned that within the last hour or two he had received a communication from the British Medical Association, and it would be hard to force the Government to pronounce upon it then. He went on to allude to the question of income limit, and remarked that it was the only question that still presented difficulty. The amendment proposing a "£2 a week limit" could, he said, be raised on Clause 14. He promised that if it was found out of order or inconvenient to discuss such matters on Clause 14 he would undertake to have Clause 8 recommitted in order that they might be debated. This pledge satisfied the House, and the amendment of Mr. JOYNSON-HICKS was withdrawn.

On Wednesday the House of Commons had the subject of the sanatorium benefit before it. The debate in its earlier stages took the shape of a general discussion on the treatment of tuberculosis, and many interesting medical views as to the best way to deal with the disease were quoted. Later a proposal was brought forward to extend the sanatorium benefit to the wives and children of insured persons. Mr. LLOYD GEORGE could not accept it owing to the additional cost which it would entail. However, he showed himself sympathetic to a suggestion that this extension of the benefit should be undertaken by local authorities, with assistance from the Treasury.

Amendments to National Insurance Bill.

Fresh amendments to Clause 14 of the National Insurance Bill dealing with the administration of medical benefit have been put on the notice paper. The important one put down by the Chancellor will be found elsewhere (see p. 194). Many of these are duplicates of amendments of which notice has already been given, and others approximate closely to the terms of those which have already been recorded. Several new amendments may be noted.

Mr. BARTON has an amendment to secure that the rate of medical remuneration is to be so calculated as to produce an amount equal to that which would be produced by private practice at the rates general in the district.

Mr. HUME-WILLIAMS will propose to insert a provision in the clause to the effect that "every Local Health Committee shall prepare a panel comprising the name of every medical practitioner in the locality who shall intimate a desire to have his name placed thereon, from which panel an insured person shall have the right to choose the medical practitioner from whom he is to receive such medical attendance as he may become entitled to under this Act. Provided that, having made such choice, the insured person shall not be at liberty to change his medical practitioner more than once in 12 months without the sanction of the Local Health Committee."

The honourable Member has given notice of another amendment in the following terms: "Every Local Health Committee shall have the power, on the request of an insured person or on that of the medical practitioner attending such person, to sanction the obtaining of a second medical opinion in regard to the patient, whether such second opinion has already been obtained or not at the time of such request; and in cases where such sanction has been obtained the expenses incident to the obtaining of such second opinion shall be met by the Local Health Committee and included in the amount provided for by Subsection (4) of this section."

A large number of amendments to protect pharmaceutical chemists have also been placed on the paper.

Amendments by the Chancellor.

Mr. LLOYD GEORGE has now placed on the notice paper several amendments relating to matters concerning the medical profession. One of those amendments on Clause 14 sets out that the Local Health Committee shall make arrangements with duly qualified medical practitioners in accordance with regulations made by the Insurance Commissioners. (See p. 194, where the amendment is printed in full.)

In an amendment which he has put down to Clause 41 the Chancellor of the Exchequer proposes that one of the Insurance Commissioners at least shall be a duly qualified medical practitioner who has had personal experience of general practice. On the Advisory Committee he also proposes that there shall be duly qualified medical practitioners who have personal experience of general practice. The Chancellor in another amendment proposes that the Local Health Committees shall consist of not less than 12 or more than 24 members. The numbers contemplated by the Bill are 9 and 18 respectively. According to a further amendment two members of the Local Health Committee "shall be elected in manner provided by regulations made by the Insurance Commissioners, either by an association of the duly qualified medical practitioners resident in the county or county borough which may be formed for the purpose under such regulations, or if no association has been formed, by such practitioners and the others, of whom one at least shall be a duly qualified medical practitioner."

Final Report of the Royal Commission on Tuberculosis.

The final report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis was issued to Members of the House of Commons on Tuesday evening. The report is signed by Sir W. H. POWER, Professor G. SIMS WOODHEAD, Professor SIDNEY MARTIN, Principal MCFADYEAN, and the late Sir R. W. BOYCE. The Commission was appointed in 1901, and the questions which it was empowered to investigate were: (1) whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; and (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances, favourable or unfavourable, to such transmission. These questions are discussed in the final report. It may be mentioned that the investigations of the Commission have cost more than £75,000.

HOUSE OF COMMONS.

WEDNESDAY, JULY 5TH.

Milk Legislation.

Mr. COURTHOPE asked the President of the Local Government Board when the Milk and Dairies Bill would be introduced.—Mr. BURNS replied: I hope to introduce the Bill in the course of next week.

New Patent Medicine Stamp.

Mr. FLETCHER asked the Home Secretary whether a new medicine stamp was being prepared which would more clearly indicate that the stamp did not imply any Government guarantee.—Mr. CHURCHILL wrote in reply: I am informed that the answer is in the affirmative.

Pulmonary Tuberculosis in Germany.

Sir J. ROLLESTON asked the Chancellor of the Exchequer whether his attention had been called to the fact that during the ten years ending 1908 the death-rate from pulmonary tuberculosis was 13·3 per 10,000 of the population of the United Kingdom and 17·9 per 10,000 of the population of that part of the German Empire for which returns had been furnished to the Registrar-General for England and Wales; and whether he could give the House information as to the cause of the higher death-rate from this disease existing in Germany despite State sick insurance there for many years.—Mr. LLOYD GEORGE replied: It is undoubtedly the case that the rate of mortality from pulmonary tuberculosis is higher in Germany than in the United Kingdom. There has been a large reduction in the death-rate from this cause in Germany since the sickness and invalidity insurance laws have been in full operation, and German authorities attribute the reduction in part to the beneficial influence of these laws upon the health of the nation, and particularly to the measures adopted, including an extensive system of sanatoria, for the treatment of consumption in the early stages of the disease. The same authorities agree that unsatisfactory conditions of life, and especially of housing, contribute largely to the existing high rate of mortality from consumption.

THURSDAY, JULY 6TH.

Medical Referees.

Mr. HODGE asked the Secretary of State for the Home Department whether he was aware that it was becoming common for medical referees under the Workmen's Compensation Act to accept fees from, and to appear as witnesses for, insurance companies in cases arising in the courts to which such referees were attached; whether his attention had been drawn to a case at Gloucester, on May 20th last, where the judge stated that, although it was a case which he naturally would have referred to a medical referee of the court, he could not do so because the referee had given evidence, and there being no power to appoint another referee he would have to act as doctor himself; and whether he could take any steps to prevent a recurrence of such incidents and secure a more impartial standing on the part of the medical referees.—Mr. CHURCHILL replied: The Home Office regulations forbid medical referees from acting for the employer or insurance company in any case in which the workman is receiving a weekly payment for compensation or which is otherwise likely to come before them as referees, and I believe these instructions are generally observed. In the Gloucester case I find on inquiry that the workman was sent to the medical referee under a mistaken impression on the part of the applicant's solicitor that Stroud was outside his district. I will consider whether an additional referee should be appointed, but it is in the power of the judge in such a case to call in a medical referee from an adjoining district.

Mr. GILL: Has the right honourable gentleman considered the question of the appointment of medical referees to devote the whole of their time to the duties, and may I ask whether he will make such appointments in accordance with the promise made by Lord Gladstone when he was Home Secretary?—Mr. CHURCHILL: I have not had the opportunity of studying the reports of my predecessor, but I will take steps to look into the matter if the honourable gentleman will put a question on the paper.

Tropical Diseases Investigation.

Dr. HILLIER asked the Chancellor of the Exchequer whether he proposed increasing the grant to tropical diseases investigation, and if so by what amount.—Mr. HOBHOUSE (Secretary to the Treasury) answered: The Treasury has recently sanctioned the appointment of a special commission under Sir D. Bruce, and including at the outset the services of Professor Newstead, to make further investigations into trypanosome diseases, the cost of which, amounting for this year alone to about £5000, will ultimately fall upon the Exchequer. In view of this large provision of money the Chancellor of the Exchequer does not see his way to increase the amount of the grants provided in the estimates for tropical diseases investigation, as Sir D. Bruce's commission will be carrying out this very work with great prospects of successful results.

Poor-law Cases in Sanatoria.

Mr. GOULDING asked the Chancellor of the Exchequer whether it would be possible for boards of guardians to send Poor-law cases to sanatoria established under the National Insurance Bill.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) wrote in reply: The position of sanatoria which are established by means of grants from the Local Government Board in regard to the accommodation of patients other than insured persons will be a matter for arrangement.

Small-pox and Vaccination in the Navy.

Dr. HILLIER asked the First Lord of the Admiralty to state the number of cases of small-pox in the Navy reported annually from 1897 to the present time; and what were the regulations in regard to vaccination in the Navy.—Mr. MCKENNA furnished the following written answer: I. Statement showing the number of cases of small-pox in the Royal Navy for the years 1897–1910 inclusive: 1897, 51; 1898, 24; 1899, 15; 1900, 13; 1901, 9; 1902, 15; 1903, 3; 1904, 12; 1905, 2; 1906, 6; 1907, 3; 1908, 4; 1909, *nil*; 1910, 1. II. Regulations respecting vaccination in the Navy: All persons entering the service are to be revaccinated; should no results follow on the first operation a second vaccination is invariably to be performed. In the case of candidates for artificer and artisan ratings the operation is to be deferred till they have been finally accepted for the service. All persons who have not been revaccinated between their first entry into the service and the age of 18 shall be revaccinated as soon as possible, however good their primary vaccination cicatrices may appear, or even should they present unmistakable evidence of having suffered from small-pox previous to that age. The revaccination is to be made with calf lymph from a recognised establishment which is carried on under proper supervision. No person shall be considered revaccinated who has had the operation performed with lymph taken from the arm of a revaccinated person, but all persons so revaccinated shall again be vaccinated with lymph taken from the sources specified above. A notation of the date of revaccination is to be made by the medical officer on each man's medical history sheet, specifying the result, whether successful or otherwise, and such cases are only to be considered successful in which either vesicles, normal or modified, or papules surrounded by areolæ, have resulted. When the first operation is followed by no result, which should, however, be rare when it has been carefully performed, vaccination should be repeated in 14 days from the first attempt. The medical officer, as soon as convenient after he joins a ship, will satisfy himself by personal inspection that each officer and man has been successfully vaccinated, and when necessary revaccinated, and so also with regard to every officer and man who may subsequently join, except those borne for disposal or as temporary supernumeraries in home ships, and whose stay in them will be but short.

MONDAY, JULY 10TH.

Medical Examination of Lead-workers.

Mr. WEDGWOOD asked the Secretary of State for the Home Department, with regard to the certifying factory surgeons for the districts of Burslem, Hanley, Stoke-on-Trent, and Tunstall, what was the number of lead-workers examined monthly by each certifying surgeon; what remuneration in respect of such work did each certifying surgeon receive annually; and did the payment include the treatment of lead-workers suffering from lead poisoning or advice as to treatment.—Mr. CHURCHILL replied: The average monthly numbers of lead-workers examined are approximately as follows: Burslem, 1400; Hanley, 1400; Stoke, 2100; Tunstall, 650. The surgeons' fees for these examinations are under the Act required to be paid by the employer, and I cannot therefore give the total amount of remuneration received for the work. The payment includes only the examination of the workers for the purposes of the special rules, and does not therefore cover treatment or any advice as to treatment, though I understand the surgeons often advise workers to obtain treatment either of their own medical man or at the North Staffordshire Infirmary. I should like to add that the chief inspector and the medical inspector of factories have a very high opinion of the manner in which the work of examination is done by the surgeons in question.

Furloughs at Netley.

Mr. PERKINS asked the Under Secretary of State for War whether the Royal Victoria Hospital at Netley was understaffed; whether recent orders limit furloughs granted to men of the Royal Army Medical Corps to 14 days, while men of other regiments going on leave to Ireland and Scotland were given six weeks, and were sure of at least a month's furlough annually; and whether leave could only be obtained when the applicant was successful in finding another man to do his duty.—Colonel SEELY said in reply: Netley Hospital staff is somewhat under establishment owing to the Royal Army Medical Corps at home being short of establishment. Consequently furloughs can only be sparingly granted, and these are being generally limited this summer to 14 days. The furlough season at Netley, however, is not, as with other troops, confined to the winter months, and the furloughs are given when the men can best be spared. It is not the case that leave can only be obtained when the applicant is successful in finding another man to do his duty.

TUESDAY, JULY 11TH.

National Insurance Topics.

Mr. ROWNTREE asked the Chancellor of the Exchequer to state the approximate number of persons that were affected by limiting those who were eligible as voluntary contributors to those whose income did not exceed £160 per annum, and the estimated saving to the fund by this limitation.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) replied: It has always been anticipated by my right honourable friend that the number of persons with incomes above £160 who would take advantage of the privilege of voluntary insurance would be small. I do not think the assumptions explained in Paragraph 17 of the actuaries' report would be much affected by the change.

Mr. JAMES PARKER asked whether, in view of the power given to the Local Government Board to utilise any Poor-law institution for the purpose of the provision of sanatoriums and other institutions for the treatment of tuberculosis or such other diseases, under Section 47 of the National Insurance Bill, clauses would be inserted in the Act to safeguard the interests of officers in such manner as was provided in Section 120 of the Local Government Act, 1888, and Section 28 of the City of London (Union of Parishes) Act, 1907.—Mr. HOBHOUSE answered: No such power is given by Clause 47 which enables the Local Government Board to make grants for the provision of sanatoriums where required.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ARCHER, E. W., L.M.S.S.A. Lond., has been appointed House Surgeon at the Bristol Royal Infirmary.

CHITTY, HUBERT, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Senior Resident Officer at the Bristol Royal Infirmary.

CLARKE, RICHARD CHRISTOPHER, M.B., Ch.B. Bristol, has been appointed House Surgeon to the Ear, Throat, and Nose Department at the Bristol Royal Infirmary.

COOKSON, HENRY ANSTEY, M.B., B.Ch. Edin., has been appointed House Physician at the Bristol General Hospital.

DUNNE, ARTHUR B., M.B., B.C. Cantab., D.P.H., has been appointed Medical Officer of Health to the Bentley-with-Arksey Urban District Council.

HOPWOOD, JOSEPH STANLEY, L.R.C.P. Lond., M.R.C.S., has been appointed House Physician at the Bristol Royal Infirmary.
KINGSTON, STUART HARDY, L.R.C.P. Lond., M.R.C.S., has been appointed House Physician at the Bristol Royal Infirmary.
MALHERBE, STEPHANUS ERNST, M.B., B.Ch. Edin., has been appointed House Surgeon at the Bristol General Hospital.
MARLE, S., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician at the Bristol General Hospital.
PICKIN, FREDERICK HAROLD, L.R.C.P. Lond., M.R.C.S., has been appointed Casualty House Surgeon at the Bristol General Hospital.
STATHAM, REGINALD SAMUEL SHERRARD, M.B., Ch.B. Bristol, has been appointed Resident Obstetric Officer at the Bristol Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDARE EDUCATION COMMITTEE.—Medical Inspector of School Children. Salary £250 per annum.
ABERDEEN, KINGSEAT ASYLUM.—Assistant Medical Officer. Salary £120, with board, &c.
AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.
BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.
BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Junior House Surgeon. Salary £70 per annum, with board and residence.
BIRMINGHAM CITY ASYLUM.—Junior Assistant Medical Officer and Pathologist. Salary £150 per annum, with board, apartments, and laundry.
BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.
BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with apartments, board, and laundry.
BURNLEY, VICTORIA HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £80 per annum, with residence, board, and washing.
CARDIFF UNION WORKHOUSE.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rations, apartments, attendance, &c.
CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.
CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £70 per annum, with board, apartments, and laundry.
CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Resident Medical Officer for four or six months. Salary at rate of £50 per annum, with board, lodging, and washing.
COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.
DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing.
DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months, unmarried. Salary at rate of £50 per annum, with board, apartments, and laundry.
DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.
ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—Honse Surgeon. Salary £72 per annum.
FULHAM ANTITUBERCULOSIS DISPENSARY.—Medical Officer. Salary £250.
FRENCH HOSPITAL, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £50 per annum, with board and laundry.
GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and laundry.
HEMEL HEMPSTEAD, HERTS, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Medical Officer, unmarried. Salary £200 per annum, with board, and residence. Also House Physician for six months. Salary 30 guineas.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon and House Physician, both unmarried, for six months. Salary in each case £30, with board, residence, &c.
LEICESTER INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, apartments, and washing.
LONDON HOSPITAL, E.—Six Honorary Dental Surgeons.
LONDON LOCK HOSPITAL.—House Surgeon to the Female Hospital. Salary £100 per annum. Also Assistant House Surgeon. Salary £60 to £80 per annum, each with board, lodging, and washing.
LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Also Assistant House Surgeon for six months. Salary at rate of £105 per annum.
LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing.
MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Honorary Physician. Also Pathologist and Registrar. Salary £75 per annum.
NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Demonstrator of Anatomy.
NORWICH, NORFOLK AND NORWICH HOSPITAL.—Two House Surgeons. Salary £80 each per annum. Also Casualty Officer, unmarried. Salary £60 per annum. All with board, lodging, and washing.
NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, &c.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing.
NOTTINGHAM WORKHOUSE INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, and attendance.
POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.
PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.
PRESTON ROYAL INFIRMARY.—Junior House Surgeon, unmarried, for six months. Salary £60 per annum, with board, residence, and washing.
PRESTWICH, MANCHESTER, COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, attendance, and washing.
PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Junior House Physician. Salary £50 per annum, with residence, board, and laundry.
ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.
ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board and residence.
ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £80 per annum.
SALISBURY, FISHERTON HOUSE ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, washing, lodging, and attendance.
SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, lodging, and washing.
SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician, unmarried. Salary £60 each per annum, with board, lodging, and washing.
SHROPSHIRE EDUCATION COMMITTEE.—Medical Inspector in the Public Elementary Schools. Salary £250 per annum.
SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing.
SOUTHEND-ON-SEA, BOROUGH OF.—Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £250 per annum.
TAUNTON, SOMERSET AND BATH ASYLUM, Cotford.—Assistant Medical Officer, unmarried. Salary £140 per annum, with apartments, board, washing, &c.
VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician and House Surgeon, each for six months. Salary £40, with board, lodging, and laundry. Also Anæsthetist. Salary £37 16s. per annnm.
WADSLEY, NEAR SHEFFIELD, WEST RIDING ASYLUM.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c.
WARRINGTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary at rate of £100 per annum, with board, lodging, and laundry.
WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.—Junior House Physician. Salary £75 per annum.
WESTMINSTER GENERAL DISPENSARY.—Resident Medical Officer., Salary £120 per annum, with rooms, attendance, &c.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.
WORCESTER COUNTY AND CITY ASYLUM, Powick.—Third Assistant Medical Officer, unmarried. Salary £140 per annum and all found.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Bexhill, in the county of Sussex; at Creetown, in the county of Kirkcudbright; and at Wigton, in the county of Cumberland.

Births, Marriages, and Deaths.

BIRTHS.

BATES.—On July 2nd, at "Westwood," Central-hill, Upper Norwood, S.E., the wife (*née* Lyon) of Joah Bates, M.R.C.S., L.R.C.P., of a daughter.
HARDENBERG.—On July 6th, at Duffield House, Watford, the wife of E. F. H. Hardenberg, M.B., M.R.C.S., L.R.C.P., of a son.
INKSON.—On July 7th, at West Kent Nursing Institution, Mount Sion, Tunbridge Wells, the wife of Major Inkson, V.C., R.A.M.C., Bangalore, India, of a daughter.
KEELING.—On July 7th, 1911, at Attleborough, Norfolk, the wife of G. S. Keeling, M.D., a son.
PARKHURST.—On July 5th, at "Rathan," Newhaven, the wife of Rodie Parkhurst, M.B., C.M., of a son.
SMITH.—On July 11th, at Richmond House, High-street, Manchester, the wife of J. W. Smith, F.R.C.S., of a son.

MARRIAGES.

LEIGH CANNEY—BETTS.—On July 8th, at St. George's, Hanover-square, Henry Edward Leigh Canney, M.D. Lond., to Kathleen Mordaunt FitzGerald, only daughter of Edward George Betts, M.R.C.S. Eng., and of Mrs. Betts.

DEATHS.

DALY.—On July 3rd, at 19, Myrtle Hill-terrace, Cork, Pierce Joseph Daly, M.D.
MENNELL.—On July 5th, at St. Thomas's Home, Zebulon Mennell, M.R.C.S., L.S.A., aged 60.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH MATTERS IN GAMBIA.

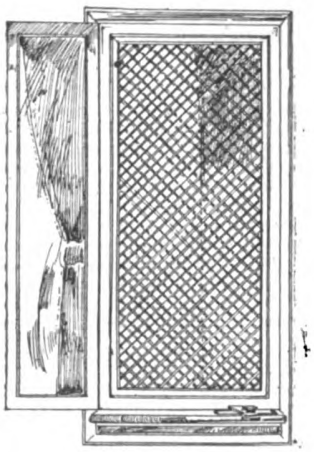
FROM the medical section of the report on the Gambia (West Africa) Blue-book for 1910, prepared by the Colonial Secretary, Lieutenant-Colonel O'Brien, C.M.G., it appears that the general health of the colony remains good.

In Bathurst, the chief town, the sanitary work is controlled by a Board of Health. During the year under notice a special grant of £1000 was sanctioned by the Secretary of State for sanitary purposes, and part of it was expended in providing sanitary dustbins for the collection of rubbish and in the erection of three incinerators for the rapid disposal of refuse, which, after being burnt, is used to fill up depressions. The board continues to give close attention to anti-malarial work in clearing watercourses and removing receptacles which might form breeding-places for mosquitoe. The Gambia now shares with the colony of Sierra Leone the services of a senior sanitary officer. The free issue of quinine mixture at the hospital to all comers, and its regular issue to all children attending school and also to members of the police force and to men of the West African Frontier Force and their wives and families continue. The public, too, are coming in increased numbers to take advantage of this prophylactic treatment. The practice of sleeping in mosquito-proof rooms or under mosquito curtains is invariable among the Europeans and is being adopted by some of the more educated natives. All Government officials are provided with mosquito-proof cubicles and also with separate mosquito-proof shelters in which they can sit and work or read during the day. This latter provision is probably the cause of the smaller number of days spent by European officials on the sick list on account of malaria during the past year and of the general improvement in their health. A considerable advance in the number of tanks which are used for the storage of drinking water, obtained from the roofs of houses, was made during the year. The public wells are gradually being fitted with Jonets water elevators, which have proved a great success, as they are very efficient in preventing pollution of the water, and, further, they render the wells fly-proof. The war against mosquitoes and the extermination of their breeding-places have been actively pursued under considerable disadvantages, but it is hoped that, with the appointment of a European town warden and a larger sanitary staff, considerable progress will be made in the current year. Lectures on elementary hygiene and sanitation continue to be given to school teachers, and a simple course is to be added to the curriculum of the school.

In the Protectorate (the population of which is roughly estimated at 152,000) the special attention of the Commissioners and the medical officer is given to the sanitation of the towns and villages, and the practice of awarding prizes to the cleanest village in each province is maintained. At the same time it is to be feared that it must be a long time before the chiefs and headmen will realise the necessity for systematic cleaning and sanitation; only in the expectation of a visit from a commissioner or the governor is anything done. A small outbreak of small-pox occurred among the men of the West African Frontier Force. Every precaution was taken, so that only three soldiers and one follower were attacked by the disease, and all made good recoveries. There were 1011 vaccinations performed in Bathurst and 336 in the Protectorate. The lymph was imported, as in previous years, from Liverpool, but although the same precautions were taken to preserve its activity the results obtained were not so good as in the previous year. The climate of the Gambia during the dry season, from the beginning of December to the middle of May, is pleasant and not unhealthy. The total rainfall in 1910 was 44·0 in. as compared with 56·99 in. in 1909. The maximum shade temperature was 104° in March and the minimum 57° in January. Victoria Hospital at Bathurst is thoroughly equipped and has 50 beds. It is now possible to segregate at a moment's notice 20 or more patients in the event of yellow fever breaking out. The establishment consists of three European medical officers resident in Bathurst, and four European nursing sisters (from the Convent of St. Joseph de Cluny in Paris) attached to the hospital, together with a native staff, consisting of a chief dispenser, four assistant dressers, and three male and two female nurses. The total admissions to the hospital during the year were 669 (of whom 22 died); out-patients, 7440. The contagious diseases hospital, situated two miles from Bathurst, proves of great service, but there is a considerable want of a quarantine station or camp. At the McCarthy Island Dispensary, 19 in-patients and 1896 out-patients were treated. The dispensary is under the charge of a dispenser, with the supervision of the Protectorate medical officer. A new hospital is now in course of construction at McCarthy Island, which will consist of one European ward, two native wards, and an isolation ward, and a resident medical officer will be appointed to take charge of it. This will be a great boon to both the European and the native population of the up-river provinces.

A NEW WINDOW SCREEN.

WE have been supplied with particulars of a new form of window screen, devised by Mrs. H. W. Morris, of 24, Minard-road, Catford, S.E., which aims at purifying the air on its admission to a dwelling room and at preventing draughts when the window is open during a high wind. The screen consists of a frame wherein are mounted two adjacent panels of reticulated material, between which is placed a sheet of muslin. The screen can be quickly fitted into the casement



of a window, or it may entirely replace the casement. It is not limited to sliding sash windows. The frame is intended to last for several years, the muslin screen being changed when soiled, or if desired the latter can be replaced by antiseptic gauze. This invention has the merit of ensuring a supply of fresh filtered air without the usual disadvantages associated with widely opened windows, and it is simple and easily adjustable.

A THERMOMETER RETAINER.

Surgeon J. Leslie Barford, R.N., of H.M.S. *Impregnable*, Devonport, has sent us the following description of a simple retainer for a thermometer:—

I have devised a very simple preventive for the promiscuous slipping out of clinical thermometers from between the lips of careless patients. It consists of about 1/8 in. of stout rubber tubing of about 3/10 in. diameter, but with a very small lumen, such as forms the essential part of a Foulis' tourniquet. This ring is moistened and passed over the bulb of the thermometer for a distance of an inch or slightly more. Many thermometers have a natural groove here. When the thermometer is put in the mouth of a patient the ring lies between the lips and teeth and is a very material help in retaining the instrument even should the lips be slightly parted. The rings cost next to nothing—one spare bit of tourniquet tubing could be cut up with a sharp knife into dozens of them. They can be detached with the greatest ease, but there is no obvious objection to their remaining on the thermometers and soaking in the disinfectant in the ward; but in this case a practical point is to employ a vessel with a brim wider than its base. Otherwise, in quickly withdrawing a thermometer, its ring may catch in that of another and drag it out of the vessel with disastrous results. This very simple device should prove useful in out-patient departments or in establishments such as a boys' training ship, where the temperatures of more or less casual patients are constantly being taken. While in use in the sick bay of my ship not a single thermometer has been broken by being dropped from a boy's mouth—hitherto a frequent accident.

CHOLERA AND PLAGUE IN THE CAUCASUS.

Mr. P. Stevens, British Consul for the district of Batoum, in his report for the year 1910, remarks that it is not surprising, in view of existing sanitary conditions in the localities concerned, that public health was anything but satisfactory. Cholera was prevalent throughout the district, in several localities in epidemic, and in others in sporadic form. The population of the Northern Caucasus suffered more from the disease than the population of the Trans-Caucasus. Cholera was exceptionally virulent in the province of Kuban, and the governments of Stavropol and Astrakhan, the polluted waters of the local rivers being principally accountable for the severity with which these districts were visited by the disease. In the Trans-Caucasus cholera did not appear to claim so many victims as in the districts just referred to, although its extension was general. Fears are entertained that a still more terrible visitation of cholera will be the direct result of last year's epidemic.

Two isolated cases of bubonic and pulmonary plague, one with fatal issue, occurred at Batoum in 1910, but the further spread of the disease was averted by the removal of the patients to the isolation wards, the adoption of stringent quarantine, and other precautionary measures. The extermination of rats was undertaken by the local municipal authorities, and rat-poisoning and rat-catching parties were organised under two medical practitioners of the town. It is difficult to give any idea as to the number of rats which they succeeded in killing, but report has it that several rats caught by them were infected with the plague bacillus. Plague also continued to be prevalent during the year in the Steppes of the government of Astrakhan, where it is reported to have carried off a much larger number of victims than in 1909.

MESSRS. ALLEN AND HANBURYS' REVISED PRICE LIST.

Messrs. Allen and Hanburys have sent us a copy of their illustrated revised general price list. The adoption of the thumb index renders this book very convenient for reference. In Section VI., under the head of general information, will be found many details of value to the practitioner, addresses of societies, nursing institutions, much practical detail as to the method of obtaining suitable cultures for bacterial vaccines and the estimation of the opsonic index, posological tables, information concerning dentition, food composition, infant feeding, urine testing, and water analysis. The advantages of various British and foreign spas are enumerated. Messrs. Allen and Hanburys will be glad to receive inquiries from interested members of the medical profession who have not received a copy.

Maryland asks whether a locum-tenent, receiving £4 4*s.* per week and board and lodging, should be insured against claims for accidents? Under the Workmen's Compensation Act, 1906, a person not employed in manual labour whose remuneration exceeds £250 per annum would not be entitled to claim for accidents. A locum-tenent receiving £4 4*s.* per week and board and residence would clearly be in receipt of an income exceeding £250 per annum, and we do not think he could be said to be employed in "manual labour." But anyone employing locum-tenents would be well advised to take up a policy of insurance.

W. F. C. W.—The legal position may depend upon the terms of the first sale. We sympathise with our correspondent in any case, but we cannot assure him that he has a legal remedy if his request that his name be removed is ignored.

Winchester.—There is no hard-and-fast line. There was more intercommunication formerly between the professions, and reciprocity in service was often the rule. Circumstances must dictate the proper course.

F. L.—We think the chances of increased neurotic conditions too remote to be worth allusion.

ERRATUM.—By an unfortunate misprint the paper on Hay Fever in THE LANCET of June 10th, 1911, written by Mr. L. Noon, has been credited in the Index under the subject "Hay Fever" to "Mr. L. Moon," but under the name of author Mr. Noon's name is properly indexed, and he is given credit for the authorship.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

We shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for July and August, 1911:—

April-October.—Rome Exhibition (United Italy's Jubilee).
,, 29th-Oct. 26th (Turin).—International Exhibition.
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th-Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
,, 12th-Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1911, which was completed with the issue of June 24th, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1911 are now ready. Bound in cloth, gilt lettered, price 16*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Lumleian Lectures

ON

A CLINICAL STUDY OF CARDIO-VASCULAR DEGENERATION.

Delivered before the Royal College of Physicians of London

BY J. MITCHELL BRUCE, M.A., LL.D. HON. ABERD., M.D. LOND., F.R.C.P. LOND.,

EMERITUS LECTURER ON THE PRACTICE OF MEDICINE AT, AND CONSULTING PHYSICIAN TO, CHARING CROSS HOSPITAL, ETC.

LECTURE III.[1]

Delivered on March 30th.

NERVOUS STRESS.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—There is no more interesting question in connexion with the etiology of cardio-vascular degeneration than its relation to nervous stress. It is concerned intimately with the problem that we who belong to the College are asked so often and so anxiously to solve—the problem of the winding-up of the life-work of the best brains in the community. Unfortunately the limited time at my disposal does not permit me to treat this part of my subject in other than a sketchy fashion. But perhaps I may as well confess that, in one way, I am thankful to relieve myself of so heavy and altogether difficult a task as a close inquiry into the effects of intellectual and emotional stresses upon the heart and vessels—both their immediate effects in the form of disturbances of sensation and action, and any secondary or remote effects of a structural kind in which these may end.

Intellectual Stress and Emotional Stress.

The ways in which the heart and vessels are influenced by and through the nervous system are multiple and complex. Purely intellectual effort raises the systolic blood-pressure for a time. Is there any evidence that when this effect is continuous day after day, as practically it must be with the most valuable lives in the country—the statesman, the scientist, the members of learned and artistic professions—it leads to damage of the circulation? Are cardio-vascular degeneration and early death relatively common in persons of this class? According to Dr. Ogle's Report to the Registrar-General for 1885, clergymen, schoolmasters, barristers, solicitors and artists (all but physicians!) have an expectation of life beyond the mean of all males. And we have happily witnessed within the last few years the great ages which many of our most distinguished men have attained. Further, the death-rate from cerebral hæmorrhage is greater per million of living population in counties—that is, in quiet country places—than in London; but possibly this curious observation may be accounted for by the fact that fewer persons survive to an advanced age in London. We may conclude that hard intellectual work does not of itself damage the organs of circulation. It is not hard intellectual work, but the circumstances under which such work is so often carried on, that may give rise to cardio-vascular degeneration. First, there is what, in a single word, is called the worry that pursues the busy man in these days. As Professor Osler says, it is the incessant anxiety and strain of public life which tells. By common consent emotional disturbances act unfavourably upon the heart and vessels. Worry, suspense, anxious anticipation, disappointment, consciousness of failure or of failing health, the "hunted" feeling that comes of overwork and arrears, regret, sorrow, despair—all such depressing influences are believed to wear out not only the nervous system, with which they are immediately related, but the cardio-vascular system as well. It is a combination of intellectual stress and emotional stress that characterises "the strenuous life"; and we are safe to believe that it is the second element that breaks down the physiological systems. Cases of overwork of this kind are met with in public men, in officers of the services—at present more particularly of the navy, and, not to mention our own profession, most commonly of all in men of business, as business is now conducted, full of incessant interruptions and readjustments of the mental processes inseparable from the use of the telephone. But this is not all. There are other unfavourable conditions of intellectual occupation familiar to us in our daily practice. A man's temperament and constitution as well as his intelligence have to be considered. There is the patient who from natural disposition, or from habit begotten of disposition, often no doubt from a sense of duty, has systematically disregarded the guiding sense of the limit of safety in nervous work, and laboured continuously, finishing all that he had undertaken, whatever it might cost him. He has enjoyed an insufficient amount of sleep, and no sort of wholesome recreation, unless it be in the form of unwise attempts to remove nervous exhaustion by severe muscular exercise at long intervals. Again, there is the man who can do nothing, however unimportant, but at high pressure, and wears out his heart and arteries years before the calm and able personality who—thanks to his temperament or training—knows how to take worries, or (if he have worries) does not worry. And there is the man whose mental outfit is essentially unable to bear the rough and tumble of the hard work of a position of responsibility into which he has been thrust. And it is not an uncommon experience to meet with men who in working hard live hard in every way: they eat hard, drink hard (or at least freely), smoke hard, and take hard exercise. Unquestionably, too, alcohol plays a part in some cases regarded as caused by nervous stress—alcohol taken to remove the sense of fatigue, to promote sleep or it may be the sense of failure, to oil the wheels of business, or, which is most disastrous of all, to enable the worker to overwork himself. Then there is such a case as this. A man of 55 retired from business some years ago. But he is head over ears in public and religious work, a willing victim of the "promoters" of local movements of every kind, and writes and worries from morning to night, and on Sunday preaches in a public hall. I find in this patient, with a highly neurasthenic expression and manner, an apical systolic murmur and cardiac enlargement, and he is quite grey and aged-looking at 55.

Arterial Degeneration in Women.

In connexion with this subject are some interesting facts relating to the relative incidence of arterial degeneration in women. According to the Registrar-General, in his Seventy-first Annual Report (for 1908), on the average of the last eight years the deaths at all ages from cerebral hæmorrhage (together with apoplexy and hemiplegia) correspond to a death-rate of 666 per million for males and of 750 per million for females. At ages above 35, as we have already seen, it accounts for the deaths of 2083 in a million men and of 2284 in a million women. In the 20 years intervening between the thirty-third and the fifty-fifth years women fall victims to the disease in greater proportion than men, whilst at ages above 55 years the mortality is higher among men. The temptation is strong to refer this remarkable liability in women to disease of the cerebral arteries to nervous influences, although many other explanations might reasonably be offered. One is also disposed to connect it with the familiar disturbances of the circulation in neurotic and hysterical women, attacks of præcordial oppression, globus, flushing, faintness, and false angina, ending often in tears and other emotional manifestations. But to return to actual disease. I might have described to you in detail, had time permitted, the characters of a series of cases of women whose hearts had given way under the stress of a strenuous life. I will mention two only, and in a few words. A woman, aged 65 years, with radial sclerosis, a double aortic murmur, apical systolic murmur, and great cardiac enlargement, had worked for years in a financial house in the City and been worried throughout at home. Positively no other cause (excepting influenza) could be obtained. A woman, aged 62 years, still alive, broke down 13 years ago with tense, thickened tortuous radials and an aortic systolic murmur, cardiac enlargement, and temporary albuminuria after harassing work as lady housekeeper at a large club. With thickened radials and enlarged hearts, and in some cases valvular lesion, there was found in such patients a history of nothing that could be reckoned a cause of the disease but years spent in slumming, in charge of some large school, in a responsible post in the City, or the like. And the symptoms of cardio-vascular disease in these patients could

[1] Lectures I. and II. were published in THE LANCET of July 8th p. 69) and 15th (p. 141) respectively.

be traced back to the symptoms of neurasthenia. In this connexion one is reminded of the occasional existence of valvular lesions in Graves's disease, and of the occasional association of cardiac disorder and disease with epilepsy; and again, migraine links up such cases as I have just mentioned with gout and high tension.

Pathogenesis.

The pathogenesis of this group of cases is complex. No doubt both the nutrition of the walls of the heart and arteries and the internal pressure upon them are disturbed. The control of the nervous centres over the myocardium and arterial walls is indirectly trophic as well as dynamic: vagus and vaso-dilator impulses are anabolic as well as regulative of the arterial pressure. But in many instances the cause of the vascular and cardiac disorder and disease can be traced back far beyond the nervous centres. Obviously it may be reflex. Or it may originate in the assimilative and metabolic disorders which we have already studied, and which, as we observed, are relatively common in sedentary individuals devoting a great part of their time to literary and scientific indoor pursuits.

[After expressing regret that time did not permit him to discuss other causes of degeneration of the heart and arteries the lecturer proceeded:—]

RELATIVE VALUE DIAGNOSTICALLY OF SYMPTOMS AND OF PHYSICAL SIGNS.

I trust that I have proved to your satisfaction that cardio-vascular degeneration regarded in all its clinical relations is not one disease, but a group of different diseases, produced by different causes and sufficiently dissimilar in their respective characters and course to deserve—indeed to demand—separate consideration, prognostically and therapeutically. You will say that this is granted: that the same conclusion can be reached more directly by simple inquiry; by learning from the patient his past personal history in detail and the history of his present illness. I would remind you that syphilis is often denied; that glycosuria is unknown to the patient, and may be absent on the occasion of the first and only examination of the urine; that gout, regular or irregular, is so common in this country that it confuses the problem; that the influence of worry and overwork in individual patients is estimated with great difficulty; and that physical stress is far more often an incidental circumstance than an essential element in the causation of cardiac and vascular degeneration. It is well, therefore, that we should have other means to guide us to a complete diagnosis—namely, clinical observations made by ourselves.

Now I will not attempt to deny that the majority of the symptoms and signs of cardio-vascular degeneration are common to all the kinds of it. We have seen that they are. But if they be intimately regarded, not individually only, but as they occur together and are relatively prominent, they often prove to be differentially diagnostic. We have seen that, judged by statistics, angina is nearly three times more frequently present in syphilitic than in metabolic degeneration of the root of the aorta; that a patient complaining of palpitation is twice as likely to be the subject of physical strain as of gouty heart.

The physical signs are of more individual value diagnostically than the symptoms. Let me remind you of some of our results. A diastolic aortic murmur was present in 60 per cent. of syphilitic cases; in a small percentage of gouty cases; never in glycosuric cases. It is a rare sign in physical strain of the heart, unless this be consequent on previous disease; it is unknown in the alcoholic heart. Putting these facts in another form, we may say that if we meet with a diastolic aortic murmur in cardio-vascular degeneration we should at once suspect syphilis, because the probabilities are two to one that it and nothing else is the cause of the aortic incompetence; and if along with it there were no mitral murmur, we should be justified in pressing an inquiry. Working on the same principle, the presence of a mitral systolic murmur directs our attention from syphilis, in which it is relatively rare, to metabolic or gouty disease, in which it is relatively common.

Enlargement of the heart without murmur of any kind, but ith feeble cardiac sounds and a thickened radial, should ake us inquire after physical strain; and if the enlargement ere found to involve the right side markedly, strain in early fe should be suspected. A ringing second sound in the ortic area or accentuation of the second sound over the tricuspid area (it may be as low as the apex) is significant of high pressure, possibly connected with gout.

So with the course and progress of the disease, according to its nature. The course of degeneration of the aorta and heart is pecularly uncertain, being beset with hazardous developments, on which it is almost impossible to reckon. But we have seen that it is not entirely indeterminate, and that the ages at which the first symptoms appear, the rate of advance, the probability of arrest, the duration of quiescence, the circumstances connected with fresh developments, and the date and manner of termination are far from uniform. Again, I grant it is true, as we have seen, that once originated—in whatever cause—arterial sclerosis and cardiac degeneration tend to develop along one line, the line of a vicious circle, so that the characters which distinguish the different kinds of it at first, their primary characters, may be lost in what might be called its secondary characters, common to all. But the importance of the differentiation on which I am insisting attaches to our attempt to control it in its earliest stage, the stage when it can be controlled.

This consideration introduces us to the last part of my subject, the applications of the conclusions that I have reached in practical prognosis and treatment.

PROGNOSIS.

All of us have to acknowledge that we find it difficult to give a definite prognosis in an individual case of cardio-vascular degeneration. Even if we have reached what I have called a complete diagnosis, do we commit ourselves with confidence to an opinion of the patient's expectation of life? It is true that if the man has made a proposal for life insurance, we unhesitatingly recommend that it be declined; his life we consider is quite insecure. But if he or his relations ask our opinion of his prospects of recovery, we too often have to satisfy them with a general reference to the uncertainty of life and health in a person of his age and history. To ourselves there is nothing more interesting in its way than to make an attempt to forecast the course of the case exactly, and to commit to writing for our own use an estimate of the value of the man's life in months or years.

Has this study of cardio-vascular degeneration, from the point of view of its origin and nature in different cases, furnished us with fresh facts which can be employed usefully in prognosis? What it has specially taught us is the importance of making proper diagnostic use of the clinical phenomena and clinical course in each case: to interpret them into etiological and pathological terms before drawing conclusions from them. The same rule is to be followed in forecasting the patient's future. Individually regarded, the symptoms and signs of cardio-vascular degeneration in its earlier stages are dangerous elements of which to construct a prognosis. A man may have an alarming attack of angina and live for years. Paralysis may occur, giving rise to grave anxiety, but prove temporary; and this experience may be repeated over a considerable period of time. I have known a man live from 73, when I first examined him and found his radials sclerosed, a systolic murmur in the aortic area, and albumin in the urine, to the age of 93, enjoying reasonably good health. It is the existence of such cases as these that accounts for the indefinite guarded prognoses which we give. The best prognostic use to make of symptoms and signs is indirect: not to value them individually, but to diagnose by them the cause and nature of the pathological process, and then to frame our forecast by these. A stout, high-coloured woman of 55 has a systolic murmur over the base of the heart. Taken by itself, it might be considered to be of prognostic significance of any kind, however unfavourable. But regarded along with a family history of gout, a personal history of migraine and eczema, and the presence of nodi on her fingers, it means nothing more serious pathologically than a little atheroma of the arch, which we are accustomed to watch for years in such patients with no unfavourable result.

The same consideration applies to the *clinical course* of the disease in our individual patients. The progress of the case does afford us better material for making a forecast than the different symptoms and signs, but when used for this purpose it should always be considered in relation to the intimate nature of the process of which it is a clinical manifestation. On the

one hand, we note with satisfaction the decline and disappearance of pain or other symptoms of activity in syphilitic aortitis under treatment. Or we watch the physical signs change in a favourable direction from week to week in a case of cardio-vascular degeneration associated with glycosuria—the impulse improves in force, the cardiac sounds improve in quality, an apical murmur disappears. On the other hand, the appearance of a fresh murmur significant of the spread of disease from valve to valve in syphilis or gout is ominous of evil and of a short life, likely to end suddenly. A man who had had acute gout at 40 was found at 54 to have very small evidence of cardio-vascular degeneration. Twelve months later, consequent on an attack of influenza, he complained of præcordial pain, and was found to have cardiac enlargement and an aortic systolic murmur. He was seriously cautioned against work by his personal medical attendant and myself, but in vain; and before another year had passed a systolic apical murmur had made its appearance, as well as physical evidence of dilatation of the aortic arch. The next three months wrought a remarkable change in this man, as indeed might have been prognosed. Dulness invaded the whole length of the sternum; the obliterative blood-pressure in the brachial rose to 230; albumin appeared in the urine, and the size of the heart increased. Still, our advice, in accordance with our prognosis based on the advance of the signs and symtoms of disease, was disregarded. After the excitement of an important business conference and attendant hospitality the patient died from cerebral hæmorrhage.

In this connexion we turn with interest to the conclusions which we have reached in our present study with respect to the prospect of arrest of activity and recovery of health or of disablement in various degrees, or of remote or early death, in the different kinds of cardio-vascular degeneration. We found, for example, that in the course of 13 years one-half of our cases of syphilis of the heart and aorta had died, and died at the early average age of 52, whilst a decidedly smaller proportion of our cases of physical strain had perished, and these at the age of 66. Again, we found that syphilis of the aortic region runs its fatal course in 5¼ years; degeneration connected with glycosuria in 12½ years, the patient dying on an average 10 years later than the victim of syphilis. I need not recount the many facts of this order which we noted in connexion with the other types of degeneration. I trust that the figures which I was able to present to you on the duration of life, the state of health, the age at death, and the manner of death respectively (and for which I have to thank many medical friends), may prove to be of some statistical value prognostically.

Some Factors in Prognosis.

There are two other respects in which a knowledge of the cause of cardio-vascular degeneration is of essential service prognostically. In the first place, each of the pathological processes that underlie sclerosis naturally has its own prognostic elements, which are liable to be overlooked if our attention is directed to the state of the circulation only. In aortitis connected with glycosuria the risk of death from diabetic coma must not be forgotten; in syphilis the risk of general paralysis or of cerebral thrombosis. In the second place, without knowledge of the cause, we are deprived of one of the principal means of judging what effect treatment may have in prolonging the life of a patient. If we recognise that mechanical stress, which we can control, underlies the disease in one case, excessive eating, which we can moderate, in a second, and hopeless alcoholism in a third, the value of life in the three patients, relatively at least, can be more readily forecast. We have seen throughout our examination of the characteristics of the different types of cardio-vascular degeneration the important part which character, disposition, and the circumstances of the individual patient play in the development and progress of the morbid process. The personal factor is of essential prognostic significance. In the first place, the patient's inheritance is all-important. Family heart is never to be disregarded prognostically, particularly in those instances in which evidences of degeneration of the organs of circulation are creeping on in a well-ordered life. A man of 45 whose father died suddenly from myocardial degeneration, and a paternal uncle from cerebral hæmorrhage, complains of dyspnœa on exertion and on first lying down; his radials are thick, visible, and tortuous, his heart is large, and there is a faint trace of albumin in the urine. He lives quietly and temperately and has always done so, but what is the value of his life in years?

Next to his inheritance, the patient's temperament has to be estimated if we are to form a sound opinion of his chance of survival with degenerated heart and arteries. Some men profit by being cautioned. A friend of my own, with all the usual clinical characters of early Bright's disease, has lived for many years working hard at his profession on a so-called non-nitrogenous diet planned on the strictest lines. Another medical friend has been stricken by the discovery that his tension is high. There are individuals who resent and despise advice; many are naturally restless and will not submit to treatment with absolute rest in bed, which is essential in some instances. The prognosis varies accordingly. Of equal importance in this connexion are a man's circumstances. After all, it is as necessary in prognosis to reckon by the conditions under which a man expects to live as by his present state of soundness or unsoundness. He may have still to work. The prospect is always unpromising when misfortune or misery has been amongst the causes of the disease, for they are likely to continue at the period of life that our patient has reached, too often attended by a consciousness of failure. And besides these, the possibility of the patient's exposure to the other causes of degeneration has to be reckoned with. I have tried to show how in syphilis, for example, another cause of malnutrition, such as alcoholism, may come into play and determine the development of activity of the morbid process. Even at and after middle age the possibility of acute disease, influenza and pneumonia in particular, and of operation must not be disregarded.

Prognosis in the Later Phase of Cardio-vascular Degeneration.

The consideration of the importance in prognosis of the patient's circumstances and of events that may befall him introduces us to the later phase of cardio-vascular degeneration and the patient's prospects when it has been reached. New influences of an unfavourable character may have been at work and broken down the precarious compensation. An attack of præcordial or anginal pain, an unexpected paroxysm of nocturnal dyspnœa, or an alarming faint, signifies that the heart has been embarrassed by some passing event—worry or a hurried walk after a full meal; or it may be that growing breathlessness or slight œdema of the ankles can be traced to some increase of physical stress. Unquestionably, some additional cause like one of these, not necessarily an increase or extension of the original degenerative lesion, often has to be reckoned with when we are estimating the patient's chances of recovery at this stage, and the prognosis must partly be based on the probability of our being able to deal with it, to remove it and its effects, and to preserve the patient against it in the future. I dwell on this subject of the importance of new or secondary causes in the production of cardiac failure in these degenerative processes because, important as they are, they are readily overshadowed by the gravity of the original disease, and disregarded prognostically and therapeutically. How liable we are when we see for the first time a man with cardiac and respiratory distress, dropsy, and albuminuria, to be carried away by the discovery of a thickened radial, a large heart, and scanty albuminous urine, and to give a grave prognosis, neglecting to inquire how he may have been spending his life lately! A few days' rest in bed and one or two smart purges may serve to restore compensation, and to open our eyes to the immediate cause of the patient's grave condition. An opinion of the prognostic significance of angina in association with cardio-vascular degeneration ought never to be given until tobacco has been excluded as a possible cause of the attack.

But this consideration must not make us unprepared for cardiac failure from genuine advance of the primary disease in the forms of slow invasion of the coronaries and fibrosis and failure of the myocardium; of sudden occlusion of the coronaries with fatal effect; of further involvement of the valvular structures, and inability of the already overtaxed and degenerated heart to meet the increased damage; or of spread of the sclerotic process into the kidneys and brain with disastrous consequences, whilst the lungs and other viscera become involved in the progressive effects of an inefficient circulation. Here, in the stage of failure, the last phase of cardio-vascular degeneration, knowledge and appreciation of the cause are as valuable as they are in

the earlier stage. And here, too, the prognostic value of the individual symptoms — dropsy, pulmonary œdema, Cheyne-Stokes breathing, tachycardia and the rest—is to be estimated most properly after their etiological, pathological and physiological significance has been interpreted. In one instance such phenomena as these may signify failure of a heart dilated many years before by physical stress and now overtaxed by some unwise effort, but with good prospect of recovery. In another instance they may be evidences of failure of the heart in a gouty case that has drifted into granular kidney, when we know that recovery is impossible. Notwithstanding these considerations and the prognostic rules that follow from them, we often do allow our judgment to be guided by some of the individual clinical phenomena. Dropsy is not always prognostic of death forthwith when developed in the course of cardio-vascular degeneration. Even alarming attacks of acute pulmonary œdema with urgent dyspnœa and abundant blood-stained frothy sputum, if they are referable to some passing cause, as we have seen, and correctly treated, may end in temporary recovery. A few weeks ago I saw a man recover from acute cerebral congestion, with alarming rise of tension, headache, mental confusion and aphasia, and sickness; but he was well depleted of blood and heavily purged. On the other hand, Cheyne-Stokes breathing in full development, with continuous restlessness in the night, the *bruit de galop*, and evidences of pulmonary infarction, are to be recognised as fatal omens. One-sided pleurisy in cardio-vascular degeneration, with slight pyrexia and the symptoms and signs of failure of the heart, is in my experience a type of failure prognostic of death; all our ordinary remedies fail, digitalis especially making no impression either on the heart or on the volume of urine, and the patient sinks in the course of a few weeks.

TREATMENT.

I have come to the last of the questions which we have kept before us in this study. Can the differentiation of the causes of cardio-vascular degeneration be turned to practical account in treatment? I will try to answer this question without engaging in any lengthened discussion. This is not the occasion for a dissertation on the treatment of cardio-vascular degeneration in general, nor even on the principles which should guide us in planning it.

First let us speak of treatment in the widest sense: preventive as well as remedial. A practitioner who keeps before his mind a conception of arterial sclerosis and cardiac degeneration as effects of different and recognisable causes connected with the habits, occupations and circumstances in general of everyday life, rather than as a single pathological state, cannot fail to be impressed with the possibility as well as the desirability of preventing them. When we review the causes that we have discussed, we are struck by the consideration that most of them, or the habits in which they originate, can be avoided. Temperance and chastity alone would prevent a large proportion of these degenerative processes. In respect of syphilis, excessive eating and alcohol, this point requires no discussion. It is more difficult to persuade the young men of the present day that they may permanently damage their hearts unless hygiene, physical and moral, accompany indulgence in their favourite sports. Nor is it much more easy to control in this respect the middle-aged man who was brought up in the same physical school, and forgets that his years, his sedentary occupation, and enjoyment of the pleasures of the table have seriously interfered with what he calls the "condition" of his heart. As for nervous influences, we have seen under the head of prognosis how difficult a task it is for us to prevent or to arrest their unfavourable effects on our patient's circulation. The family practitioner has here abundant opportunities of exercising his judgment, tact and personal influence over his patients.

When the cause is already at work, the sooner its nature is identified and attention paid to the indications for treatment that it furnishes, the better is the prospect of arrest and of possible recovery. Let us review what these indications are according to the clinical type of the case when the disease is still in its earlier stage—that is, before failure of the heart has set in. Management of the case it its last stage is practically the same whatever the nature of the degenerative process may have been.

Syphilitic Disease of Heart and Aorta.

In our study of syphilitic disease of the heart and aorta we discovered certain characters peculiar to it and diagnostic of it. Each of these furnishes us with special indications for treatment. Its cause—a parasite—is to be destroyed if possible, or controlled in its activity. This we attempt to do with specific drugs, particularly mercury and iodide of potassium. At the same time we must not neglect to make full use of the very important observation that the destructive activity of the spirochæta on the root of the aorta is promoted in middle and old age by the incidental association with it of certain pathogenetic influences that come into play at that period of life, particularly alcohol, gout, and other disturbances of nutrition, and the stress of circumstances, just as physical stress assists it in early manhood. Manifestly one of our first concerns in the management of the victims of syphilis contracted in youth will be to protect them against these other influences by serious and timely counsel; and, if aortic degeneration has already made its appearance, to remove or reduce such influences as speedily as possible. A third characteristic of this kind of degeneration is its selection for its field of activity of that part of the arterial system most exposed to the stress of the ventricular systole. To diminish the disposition of syphilitic arteritis to spread locally, and with a view to promote repair of damaged parts on ordinary therapeutical principles, rest—comparative rest of the heart and great vessels—is indicated. If pain and extension of the physical signs prove that the process is dangerously active the patient is sent to bed. When symptoms are of moderate severity, restricted movement, guided by the patient's sensations and common sense, will usually suffice. But he must be kept under close observation, particularly if he continues to work, as he may be allowed to do in many instances. Physical examination will usually keep us informed of the course that the disease is following, and enable us to act without delay if there be evidence of extension. This would call for absolute rest and larger doses of specific drugs. But occasionally we are too late. One of my patients died suddenly who had been allowed to walk about quietly because he suffered from pain only when actually at business. At the same time the general principles that direct our treatment of cardiac disease of every kind are respected. Diet is sufficient, and of a kind that promotes repair; the patient's comfort is not forgotten, and his individuality receives particular consideration in view of the bodily and mental restrictions to which he is asked to submit. As I said in my first lecture, the treatment of syphilitic degeneration of the aortic area on these principles is immediately successful in many instances. The rate and degree of improvement are often remarkable. A man of 62 with syphilitic aortitis and mediastinitis so active that he had alarming attacks of stenocardia, lost all symptoms on the treatment just described, combined with mercurial inunctions; rapidly gained 21 lb. in weight, and within two years was blest with a son and heir to his property. Another patient gained a stone on 20-grain doses of iodide of potassium four times a day for three months. Results like these are unmistakeable.

Glycosuric Cases.

Leaving syphilis, let us see what guides to treatment we have found in the etiological and clinical relations of cardio-vascular degeneration associated with glycosuria. As the pathological and clinical characters, so the indications for treatment which flow from them are unlike those which we have just discussed. The morbid process is generalised throughout the circulation. The heart and vessels, as well as the nervous and other structures, are continuously fed with impure blood, the product of malassimilation, associated often with excessive eating. The heart in particular proves to be badly nourished and asthenic, with consequent incompetence of the mitral. The arterial tension is low in correspondence. Here there is no indication for giving specific drugs unless it were codeine in fully developed diabetes. What is indicated is thorough reform of the patient's manner of living. Habits of self-indulgence in food or drink, with indifference to the result, must be broken. To effect this end strong-handed action is required of the practitioner, for you remember that he may have a headstrong, masterful man to deal with. The diet has to be reduced in amount, and the constituents of it planned according

to ordinary rules for the removal of sugar from the urine. In but a small proportion of cases is it necessary to resort to strictly antidiabetic diet—to forbid bread, for instance. Nor is it necessary to forbid meat, although there is a trace—possibly more than a trace—of albumin. The morbid characters of the urine suggest overflow of two essential constituents of tissue nutriment, sugar and albumin, from excessive ingestion and derangement of the assimilative processes through overwork of them. Vichy water should replace alcoholic drinks and be taken freely in the early morning. In these glycosuric cases correct appreciation of their nature teaches us that exercise—not rest, as in syphilis—is called for, graduated exercise on foot in different forms, of which golf is one of the best, according to the patient's condition and circumstances. But caution must be observed in the use of the exercises and movements to which these patients often inconsiderately resort at the present time. Massage is valuable when salutary muscular exercise cannot be taken—for example, by stout women living in a town. Of drugs, the best, in my opinion, for cases of this kind is the classical Gregory's mixture with an extra dose of alkalis, night and morning, and a combination of arsenic and nux vomica after meals, the former mixture alone to be given for the first fortnight of treatment. In other cases an occasional mercurial purgative, followed by a saline, may be substituted. A course of treatment at Vichy or Royat, under a careful and firm doctor who has been duly informed of the state of the patient's circulation, often is of real benefit; but the usefulness and safety of spa treatment in this and in every kind of cardio-vascular degeneration are limited by the age of the patient and the degree of unsoundness of his circulation and kidneys.

Gout and Cardio-vascular Degeneration.

Gout as a factor in the production of cardio-vascular degeneration introduced us to high blood-pressure. This element in the case indicates certain modifications in the treatment which I have just recommended in the glycosuric type. We have seen that the disposition of the blood-pressure to rise in gout is difficult to control—possibly because it is an inherited or family, rather than an individual, character. But the attempt to reduce it must be made; the danger of nephritis and widespread sclerosis is never to be lost sight of. The two most useful measures in these gouty cases are reduction of food in amount and in nitrogenous value, and the habitual use of purgatives. But I need not enter further into the details of the management of this most common of the dyscrasias we have to deal with in England. Iodide of potassium, combined with the bicarbonate or with the compound rhubarb mixture which I have just mentioned, is given with benefit in definite courses from time to time. Whichever of the many excellent spas at home and abroad may be selected in the season, let me repeat that the local physician must be informed of the condition of the heart and arteries and kidneys of the individual patient committed to his care. As for exercise, the gouty man, with or without early degeneration of his arteries, usually requires to be restrained rather than encouraged. He is often by disposition and early associations inclined to outdoor sports of different kinds; and when he has reached or passed middle age, will not recognise his failing powers, but will try to keep pace with younger men. This is a matter that calls for full discussion with the patient and definite settlement.

Physical Strain.

Reference to the control of exercise in the treatment of cardio-vascular degeneration introduces us to the subject of the management of physical strain of the heart and arteries. The guiding indication here might appear to be simple: to limit muscular exercise to the reduced capacity of the heart and vessels—this and nothing more. But it is not so. We found that the man who had strained his heart acutely in youth sometimes proves to have inherited but indifferent tissue material; and that the after-history of his case, as it is unravelled when he comes to us distressed in middle life, commonly includes evidences of supervention of disturbances of the nutrition of the walls—by gout, alcohol, tobacco, work, or other causes. And similarly, although in the reverse order, strain of the senile heart is most commonly consequent on nutritional disorder, possibly disease, of the myocardium and arterial coats. Therefore, whilst the principal advice which we give patients belonging to these types is to live within their means, physically speaking, that is, to be guided in work and exercise by the sense of discomfort in the chest which is a ready and sufficient signal if respected, but one which must not be provoked too often, we do not forget to direct their manner of life as a whole. For the condition of dilatation with sclerosis of the heart and arteries characteristic of physical strain no medicine is directly indicated, but small doses of digitalis and strychnine are usually given from time to time. Massage, carefully graduated resistance movements, and well-planned baths are calculated to benefit the cardiac walls in this type of case. Special attention must be paid to the diet. Men who have strained their hearts by physical exercise have commonly strained their lungs as well; and the degenerated and feeble heart is caught between the dilated lungs, which displace it downwards, and the flatulent stomach, which encroaches upwards on the thoracic space.

Nervous Stress.

To give useful advice to a man whose heart and vessels present evidences of wearing out from nervous stress is a far more difficult task than any of the preceding. It involves many considerations of an order other than pathological and medical, and yet inseparably associated with the origin of the patient's disablement and the prospects of success. The subject is, indeed, far too complex to be discussed here. The physician or practitioner who undertakes this responsible duty should possess not only professional knowledge, based on experience, but an intimate acquaintance with the affairs of life, and as far as possible an insight into the character, disposition and circumstances, personal, domestic and public, of the individual. We have seen that there is little ground for the fear that intellectual stress causes cardio-vascular degeneration. But whilst it is not always necessary, and frequently is highly inadvisable, to stop work altogether, occupation has to be definitely controlled. There must be a limit to the amount and length of even purely intellectual work; sufficient provision must be made for sleep, recreation and distraction, and the use of artificial aids to work strictly forbidden, if the cerebral vessels are already unsound from any cause. And it must not be forgotten that mental occupation in the form of business or public meetings may at an unexpected moment provoke emotional excitement in the form of vexation or passion, which all authorities recognise as dangerous. But after all, worry, with work or without work, is by far the most common nervous influence to which cardiac and vascular degeneration can be traced, directly or indirectly. How difficult it is to free the patient from worry; how rarely it is at all possible, everyone knows, lay as well as professional. Still another indication is to find occupation for the man who is being taken, permanently it may be, from the sole interests of his life. Only too often the attempt is a failure, and the patient pines and dies. He is a fortunate man who finds himself in the last years of his life still provided with material as well as with the disposition and capacity for interesting occupation of his time.

General Remarks on Treatment.

If we now review for a moment the indications which we have found under the different kinds of cardio-vascular degeneration, I believe you will agree with me that the subject of treatment appears in a more satisfactory light than when it is regarded from the point of view of a single substantive disease. The result in many instances is good for a time; the figures which I have given prove this. The nutrition of the cardiac and vascular walls improves, and pressure is kept within moderate bounds, and thus the natural resistance and provisions for compensation with which the organs of circulation are endowed are successfully maintained. The management of the case now consists in retaining the control which we have gained of the cause of the disease, and in resisting as long as possible the growing dangers for which we must be prepared, as we have seen under prognosis. Whatever its origin, degeneration is essentially progressive—slowly or rapidly. The patient is past his prime; treatment must be carefully adapted to the circumstances of advancing age. The original cause may be still at work, as in gout, or it may be dormant only, like syphilis—ready to renew its activity on occasions favourable to itself. Specific measures cannot always be safely omitted. The patient is beset by the incidental circumstances and events of life—professional, social, and domestic—to which I have frequently referred as causes of occasional embarrassment and distress threatening

compensation, whether by affecting the nutrition of the walls or by raising the blood-pressure. The syphilitic subject develops gout or nephritis. The glycosuric subject meets with misfortune in business, or he is tempted to eat heartily again, and narrowly escapes death in an attack of paroxysmal dyspnœa. The gouty man foolishly taxes his enlarged heart in a fit of determination to cure himself with active exercise. Here we see necessity for observant supervision of the patient's whole manner of living. It is surprising how largely success in treatment, like success in prognosis, depends on a correct appreciation of these secondary causes of cardiac embarrassment. A man believed to be dying from acute failure of the heart and pulmonary œdema, in this stage of cardio-vascular degeneration, has been rescued by active purgation and temporary starvation.

But meanwhile vicious circles form and increase in area and in number, slowly but steadily sapping the nutrition and vigour of the heart. In my first lecture I pointed out that degeneration of the heart and vessels once commenced, necessarily—indeed, naturally—advances and ends in death. For a time treatment is so far successful as to retard the progress of disease and prevent or relieve disorder and distress. But sooner or later it ceases to benefit; and if the patient does not perish suddenly, or from cerebral hæmorrhage or Bright's disease, or in one or other of the ways which we noticed in connexion with the different causes, treatment comes to be required in a new direction—for failure of the heart. Even now it is incorrect to neglect entirely the original cause of the disease. But by this time, as a rule, the condition of the patient is too complex for much good to be expected from dissociation of its elements—the primary degeneration, the effects of additional causes of disturbance, the widespread involvement of the circulation and viscera in vicious circles. But the principle that has guided us throughout this study is still to be followed. Failure of the heart must have an immediate cause, and this often can be discovered and dealt with successfully, for temporary recovery is still not impossible. Cardiac dropsy not infrequently yields to rest, correct diet, faithful nursing, and well-planned medication in these cases of old degenerated hearts and sclerosed vessels. Even now it is not always too late to use digitalis or its allies; the circulation may still respond to them.

At last there is an end to the success that so often rewards a rational view of the nature of cardio-vascular degeneration, and the therapeutical management of it on rational principles. Little can be done now but to try to secure euthanasia for a patient dying with cardiac and respiratory distress; to order diet and hypnotics, and, most difficult of all, to make proper use of morphine, to afford what relief we can to the heart which has been maintaining a brave fight against great and ever-growing evils for so many years.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co. announce for immediate publication "Diseases of the Nose and Throat (including the Trachea and Œsophagus)," by Dr. StClair Thomson.

OUTBREAK OF SMALL-POX AT WALLASEY.—Five cases of small-pox have been reported at Wallasey, one of which is announced to have proved fatal. It appears that a girl living in Liscard was taken ill, but not so seriously as to necessitate medical attention. She was suffering from a very mild form of small-pox and soon recovered. The girl's father had arrived in the Thames on board a vessel whose captain had to report small-pox among the crew. As no record could be found of the receipt of any notification at Wallasey, further inquiries were made, and it was discovered that the Port of London authority had sent the letter to Liskeard in Cornwall by mistake. A few days later a medical man notified what appeared to be a mild type of small-pox. The medical officer of health ordered the removal of the patient to the isolation hospital. Thence he proceeded to an institution in Egremont, where the girl had been employed, and discovered three other cases—two girls and a man. Only one was serious—a girl aged 22 years—and the trio were also conveyed to the Leasome-road institution. The girl died on July 5th. The inhabitants of the district are applying for vaccination.

ON THE DIFFERENTIAL DIAGNOSIS OF OVER-DISTENSION OF THE LUNG AND PNEUMOTHORAX.

BY HUGH WALSHAM, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER TO THE ELECTRICAL DEPARTMENT OF ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE object of this short paper is merely a "differentiation" or an attempt to diagnose during life between an over-distended lung and pneumothorax. Undoubtedly the credit of first pointing out that partial compression of a bronchus may lead to over-distension of the lung belongs to Dr. G. Newton Pitt. In the Bradshaw lecture for 1910 on the Results of Bronchial Obstruction Dr. Pitt points this out, and mentions two cases in which this condition was mistaken for pneumothorax.[1] One of these cases I remember well, as it occurred in Victoria Park Hospital during my tenure of office as an out-patient physician. The case was supposed to be one of aneurysm and pneumothorax. That was as long ago as 1902. Since then we have become more critical in reading our skiagrams. I shall not refer further to the case as it is fully reported in Dr. Pitt's lecture. In the future I think that an X ray examination of the chest will discriminate easily enough between an over-distended lung and a pneumothorax. In the pneumothorax the shadow of the collapsed lung can always be seen, while in the over-distended lung, of course, it is never so seen.

I will now take a few examples. Let us first take a typical example of a pneumothorax such as is shown in Fig. 1.[2] This skiagram is from a case of pulmonary tuberculosis complicated by a pneumothorax on the left side. The diaphragm on the affected side is displaced downwards. This, however, is of no value in the differential diagnosis, because it may equally be so displaced in over-distension. The shadow of the partially collapsed left lung is well seen. The heart is displaced completely to the right and obscured by the massive tuberculous infiltration of the right lung.

We will now take another example, Fig. 2. The skiagram is from a case of pulmonary tuberculosis with a left pneumothorax. The mediastinum and heart are displaced to the right. The shadow of the collapsed lung is well seen somewhat resembling the foregoing case. Again, look at Fig. 3, a case of traumatic pneumothorax. Here again we see the shadow of the completely collapsed lung lying beside the spinal shadow. Once more, look at Fig. 4. The skiagram is from a case of pyopneumothorax. The level of the pus is well shown, also that of the collapsed lung.

I might go on multiplying examples, but the above must suffice. Of course, the shadow of the collapsed lung varies much, this variation no doubt depending on the cause of the collapse. A densely infiltrated tuberculous lung cannot, of course, completely collapse, as is well shown in skiagrams 1 and 2. Skiagram 3 shows the organ completely collapsed. But however much the shadow may vary it is always there.

I will now give two examples of over-distension of the lung from partial compression of a bronchus. On reading Dr. Pitt's lecture I at once looked through my collection of skiagrams of aneurysm and found two which I think leave no doubt as to the condition. Take Fig. 5 of an aneurysm of the transverse and descending aortic arch, notice the increased clearness of the intercostal spaces, the difference in the slope of the ribs, and the absence of the shadow of collapsed lung. Take, again, Fig. 6; here the difference in the slope of the ribs is more marked than in the previous example. There is here, also, increased clearness of the intercostal inner spaces and the absence of the collapsed lung shadow. I do not think over-distension of a lung from partial compression of a bronchus is a common condition, but that it sometimes occurs there can be no doubt.

I have added small key diagrams to the skiagrams so that my readers may follow the description more easily.

THE PERMANENCE OF THE CURE OF SYPHILIS BY "606."

BY JAMES McINTOSH, M.D. ABERD.,
GROCERS' RESEARCH SCHOLAR;
AND
PAUL FILDES, M.B., B.C. CANTAB.,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL.
(*From the Bacteriological Laboratory of the London Hospital*—Dr. W. BULLOCH.)

WE have recognised from the first that the clinical value of "606" in the treatment of syphilis required little further corroboration. Even when applied by the intramuscular method it has always appeared to us to be a substance more potent in the alleviation of symptoms than, perhaps, any other in medicine. It has, therefore, been our aim to test in particular its claims to exert a "*Therapia magna sterilisans*"—in other words, to find out to what degree it is capable of sterilising the body or completely curing a syphilitic individual by one course.[1] With this end in view we have considered it necessary to make a large number of observations on each person treated, in many cases weekly during the first two months, in order to have continuous information both of the clinical condition and the state of the Wassermann reaction. We have, therefore, selected a small number of hospital patients, not from the point of view of their clinical condition, but solely from the likelihood of their continued attendance at the hospital for the purposes of observation.

We are aware that these observations do not prove whether a patient is capable or not of cure, but they represent facts from which certain conclusions may be drawn and are preferable to the general discussions unsupported by practical tests which have figured so largely in the literature.[2 3 4]

Our cases are divided into two classes: (1) cases treated by intramuscular and subcutaneous injections; and (2) cases treated by intravenous injections. We may state that every case of relapse which has occurred among our patients has been included in this series, but of other cases only those which have been continuously observed in a satisfactory manner for a period not less than three months and not greater than 12 months. Congenital syphilitics and certain others are also not included. No case has received mercury or any other form of treatment.

INTRAMUSCULAR AND SUBCUTANEOUS INJECTIONS.

TABLE I.—*Primary Syphilis.*

Case.	Amount of "606" in initial course.	Period (weeks) during which Wassermann reaction remained positive after first course.	Number of relapses.	Date of first relapse after first course of "606" (weeks).	Whether re-injection was practised or not.	Final state of Wassermann reaction.	Period (weeks) during which the final negative reaction has been observed.	Total period of observation (months).
8	0·6	2½	0	—	—	Neg.	34	9
2	0·3	2½	3 S.S.W.	5	Yes (2)	Pos.	—	11
32	1·2	9½	0	—	—	Neg.	14	6
18	0·9	3½	0	—	—	,,	29	8

A more complete understanding of the table may be obtained from the following explanation. The first column gives the reference number of the patient. The amount of "606" given in the initial course was applied in one, two, or three doses during a period usually not exceeding seven days. The third column gives the shortest period in which the Wassermann reaction became negative. The type of reaction carried out by us is the original reaction as improved by Boas. The figures in the fourth column show the number of separate relapses which have taken place; the letter "S" signifies a relapse with symptoms, and the letter "W" a relapse of the Wassermann reaction without symptoms. The fifth column shows the number of weeks after the first course of "606" at which the first relapse took place. The next column shows whether re-injection of "606" was carried out. A reinjection usually implies a course of more than one dose; when more than one re-injection is indicated this implies more than one course of, perhaps two doses. The seventh column shows the result of the Wassermann reaction at the present time, and when this result is negative the next column gives the time in weeks during which this negative reaction has been present.

Of the four cases of primary syphilis shown above, three, in our opinion, may reasonably be looked upon as cured. It would be surprising if a case of primary syphilis were to develop secondary symptoms after a period of six months.

TABLE II.—*Secondary Syphilis.*

Case.	Amount of "606" in initial course.	Period (weeks) during which Wassermann reaction remained positive after first course.	Number of relapses.	Date of first relapse after first course of "606" (weeks).	Whether re-injection was practised or not.	Final state of Wassermann reaction.	Period (weeks) during which the final negative reaction has been observed.	Total period of observation (months).
1	0·3	3	2 S.W.	13	Yes (2).	Neg.	4	12
26	1·1	10	0	—	—	,,	20	7½
28	1·1	4	1 S.	5	No.	,,	18	7
24	0·8	11	0	—	—	,,	20	7½
12	0·6	—	1 S.	8½	Yes.	,,	19	9
30	1·0	—	1 S.	4	No.	Pos.	—	7
15	0·5	—	2 S.W.	11	Yes.	,,	—	8½
21	0·9	9	0	—	—	Neg.	23	8
4	0·6	14	0	—	—	,,	24	9½
6	0·5	7	1 W.	14	Yes.	,,	4	9½
22	1·1	8	0	—	—	,,	24	8
3	0·4	—	1 S.	9	No.	Pos.	—	2½
5	0·5	—	1 S.	17	,,	,,	—	9½
9	0·6	6½	0	—	—	Neg.	12	4½
25	0·5	13	0	—	—	,,	17	7½

From the foregoing it would appear that the intramuscular application of "606" exerts a somewhat variable effect upon the Wassermann reaction in secondary syphilis, due no doubt to an incomplete therapeutic action. It will be seen that five of the 15 cases did not become negative, and all five relapsed. Of the remaining 10 which became negative three relapsed and seven did not. Thus one-half of these cases relapsed. The average period required to obtain a negative reaction was 8½ weeks, and the average period at which relapse occurred was 10 weeks, while the longest was 17 weeks. Case 28 became spontaneously cured of his slight relapse (orchitis), and the reaction, which became positive during the attack, returned again to negative a few weeks afterwards. In all cases the symptoms of relapse were very slight, while in one (Case 6) no symptoms were detected. We conclude that intramuscular and subcutaneous injections are of relatively little value in the treatment of secondary syphilis.

TABLE III.—*Tertiary Syphilis.*

Case.	Amount of "606" in initial course.	Period (weeks) during which Wassermann reaction remained positive after first course.	Number of relapses.	Date of first relapse after first course of "606" (weeks).	Whether re injection was practised or not.	Final state of Wassermann reaction.	Period (weeks) during which the final negative reaction has been observed.	Total period of observation (months).
17	0·8	—	1 S.	14	No.	Pos.	—	3½
31	0·6	—	1 S.	4	Yes.	Neg.	12	6
19	0·9	—	1 W.	12	,,	Pos.	—	8
24a	1·0	—	0	—	No.	,,	—	7½
29	0 6	—	0	—	,,	,,	—	7
7	0·6	Neg. at outset.	1 S.	14	Yes.	Neg.	18	8
27	0 8	6	1 S.	10	,,	Pos.	—	7
23	0·6	—	0	—	No.	,,	—	7½
16	0·4	—	1 S.	10	,,	,,	—	8
33	1·2	—	0	—	,,	,,	—	5½
11	0·6	—	0	—	,,	,,	—	9

In tertiary syphilis intramuscular injections of "606" have very little effect upon the Wassermann reaction, a

result which is comparable to that observed in the case of mercury. Only one case became negative and the reaction was feeble at the outset. In two cases, however (Nos. 31 and 7), exacerbations of the reaction due to relapse were reduced to negative by re-injection. Six of the 11 cases relapsed in an average period of 10½ weeks after treatment. It might have been expected that in the chronic forms of syphilis relapses would have occurred at a much later date, but apparently tertiary syphilis, being more difficult to cure than secondary, is more liable to relapse. We conclude that intramuscular injections of "606" are relatively unsuitable for the treatment of tertiary syphilis.

It must be clearly understood that this apparently unfavourable opinion is due to the fact that we reject absence of symptoms as an index of the cure of syphilis. We are content only in a permanently negative Wassermann reaction. All cases have been "cured" clinically by intramuscular or other methods.

INTRAVENOUS INJECTIONS.[5]

In many cases part of the stated amount of "606" was injected intramuscularly, a procedure which we have since omitted:—

TABLE IV.—*Secondary Syphilis.*

Case.	Amount of "606" in initial course.	Period (weeks) during which Wassermann reaction remained positive after first course.	Number of relapses.	Date of first relapse after first course of "606" (weeks).	Whether re-injection was practised or not.	Final state of Wassermann reaction	Period (weeks) during which the final negative reaction has been observed.	Total period of observation (months).
52	1·4	7½	0	—	—	Neg.	9	4
40	1·0	10?	0	—	—	,,	10?	5
55	1·4	8	0	—	—	,,	8	4
49	1·4	6½	0	—	—	,,	10	4
58	1·7	4	0	—	—	,,	10	3½
48	1·4	12½	0	—	—	,,	0	3
35	1·3	7½	0	—	—	,,	15	5½
57	1·5	?	0	—	—	,,	?	3
41	1·4	6	0	—	—	,,	14	5
38	1·0	6	0	—	—	,,	16	5½
36	1·1	6	0	—	—	,,	16	5½
46	1·4	8	0	—	—	,,	11	4½
61	1·4	8	0	—	—	,,	9	4
39	1·4	6	0	—	—	,,	14	5
50	1·4	4	0	—	—	,,	13	4

In every case the Wassermann reaction became negative after treatment, the average period, seven weeks, being little departed from. No relapses have occurred among the 15 cases and they have been observed for at least three months. We therefore conclude that intravenous injections of "606" are admirably suited to the treatment of secondary syphilis.

TABLE V.—*Tertiary Syphilis.*

Case.	Amount of "606" in initial course.	Period (weeks) during which Wassermann reaction remained positive after first course.	Number of relapses.	Date of first relapse after first course of "606" (weeks).	Whether re-injection was practised or not.	Final state of Wassermann reaction.	Period (weeks) during which the final negative reaction has been observed.	Total period of observation (months).
61	1·0	—	0	—	—	Pos.	—	3
56	1·2	13	0	—	—	Neg.	0	4
43	0·8	11	0	—	—	,,	9	5
58	1·7	—	0	—	—	Pos.	—	3
42	1·4	—	0	—	—	,,	—	5
37	0·8	—	0	—	—	,,	—	3

In two of these six cases the reaction became negative, while in all there has been a marked quantitative diminution in the strength of the reaction, a diminution which still progresses. No case has relapsed during a minimum period of three months. We therefore conclude that, as in the case of secondary syphilis, intravenous injections of "606" are suited to the treatment of tertiary syphilis.

General Conclusions.

1. Intravenous injections, so far as is known at the present time, have fulfilled all that has been claimed for this form of treatment. They appear to be very admirably suited to the treatment of syphilis.

2. Forms of application other than the intravenous are relatively unsuitable.

We wish to express our thanks again to Professor Ehrlich for the supply of "606," and to Dr. W. Bulloch for his sustained interest in the work. We are much indebted to Dr. J. H. Sequeira in particular for the liberal provision of his beds.

ACUTE DILATATION OF THE STOMACH.

AN ACCOUNT OF SIX ADDITIONAL CASES, AND A CONSIDERATION OF THE CAUSE OF THE CO-EXISTING DUODENAL OBSTRUCTION.

BY CHARLES R. BOX, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN, WITH CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL; PHYSICIAN TO THE LONDON FEVER HOSPITAL;

AND

CUTHBERT WALLACE, F.R.C.S. ENG.,

SURGEON, WITH CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

THE object of this short communication is to adduce fresh clinical evidence of the presence and nature of the duodenal obstruction which exists in acute dilatation of the stomach. Since our last communication on the subject in 1901[1] nine fatal cases of the condition have, in one way or another, come under our observation. Of six of these we now give the particulars; in the remaining three the notes and post-mortem details are imperfect, so that nothing is to be gained by their narration. In May, 1898, when recording a case of acute gastric dilatation which followed a blow on the epigastrium, we could only find accounts of 17 fatal cases; these we abstracted, and they were published in the reports of the Clinical Society of London for that year. In 1906 Dr. Lewis A. Conner published an exhaustive paper on the subject in the Transactions of the Association of American Physicians. He was then able to collect no less than 102 cases, of which 72 were fatal. No doubt additional cases have been reported since that date.

The matter is now at a stage where the mere repetition of examples is of no advantage unless they are such as either throw fresh light on the causal agencies at work, or mark some improvement in the methods of dealing with the catastrophe. Most of the later writers, recognising that the dilatation is not confined to the stomach, have accepted the hypothesis of duodenal obstruction as, in part at least, accounting for the symptoms. In a short article which appeared in THE LANCET of Nov. 9th, 1901, whilst pointing out that the idea of pyloric spasm was untenable, both on account of the bilious vomiting which is so characteristic, and also on account of the dilatation of the duodenum which is found after death, we expressed our adhesion to the notion that duodenal obstruction in some form must be present. Up to that time, to our knowledge, but two forms of obstruction had been suggested as possible—one caused by flexion of the duodenum due to prolapse of the weighty and distended stomach; the other due to mesenteric traction, the mesenteric vessels being dragged taut across the transverse part of the duodenum by the weight of the collapsed

[1] THE LANCET, Nov. 9th, 1901, p. 1259.

small intestine, which in such cases is found prolapsed into the true pelvis.

We were led to search for a different cause of duodenal obstruction by the observation that in one of the new cases we reported at that time the duodenal distension could be traced quite beyond the point where the mesentery crossed the bowel. This cause we found, after experiments on the cadaver, to be the pressure exerted by the superincumbent and dilated stomach on those parts of the duodenum which lie in contact with the front and left side of the spinal column. We learned later that a somewhat similar suggestion had been made by Meyer in 1889 and by Schultz in 1890. Our hypothesis is that in the production of the train of symptoms associated with acute dilatation of the stomach a vicious circle came into play; first a paralytic dilatation of the viscus occurred, and then distension, due to duodenal obstruction, induced by the weight of the superincumbent stomach.

Since we propounded our idea the matter has been further investigated by Conner. In three of a series of ten experiments he was able to verify the mechanism we had described. He also recognised the pressure of the stomach as a partially contributing factor in some of the others, but in the rest it exercised no effect in producing duodenal obstruction. Conner's experiments were carried out after removal of the small intestine, a weighted cord being attached to the mesentery to represent the tractive factor, so in his trials it was *only where mesenteric traction failed that the mechanism we postulated was brought into play.*

That mesenteric traction compression is a possible concomitant of gastric dilatation is proved beyond cavil by the example recorded by Baumler, in which, on that part of the duodenum which ran under the root of the mesentery, was found a band of bright red colour and two centimetres broad; the duodenal mucosa corresponding to this band showed superficial necrosis. For the pressure of mesenteric traction to act most advantageously on the duodenum the small intestine must not only be contracted, but also prolapsed into the pelvis. Then the mesentery and the contained mesenteric artery become applied to the prominent lumbar curve of the spine in a manner comparable to that in which a cord sits on its pulley. This adaptation renders compression of the duodenum very effective, and the nearer the transverse part of the duodenum lies to the greatest prominence of the curve, the greater the compression effect. A duodenum which lies lower than the average and crosses the fourth instead of the third lumbar vertebra should therefore, as Conner points out, suffer more severely from traction compression. This is of interest in view of the fact that Glénard has invoked mesenteric traction as a contributing factor in producing the symptoms of enteroptosis. Conner, from a consideration of the cases which he collected, came to the conclusion that obstruction of the duodenum by the mesentery must be regarded as present in a large proportion, perhaps from one-third to one-half, of all cases of acute dilatation of the stomach. Our experience would not lead us to adopt the higher figure at all events.

Attempts, in which we have joined, have several times been made to put the hypothesis of a duodenal kink to experimental proof. By forcible inflation of the stomach, both with air and with water, flexions and slight torsions of the duodenum may be produced. These usually occur near the point of attachment of the hepato-duodenal ligament (free edge of the lesser omentum) but may be produced at a lower level. They are uncertain in their occurrence and do not appear to exercise much obstructive effect. Post-mortem evidence does not show that they are of much clinical importance. There is some evidence that obstruction may be caused by flexion or torsion at the duodeno-jejunal junction. In a case reported by Petit a sharp kink was discovered at this spot, and on relief of the obstruction the gastric symptoms disappeared.

The new cases, which we now, by the courtesy of our colleagues, report, support in the main our former contention that the pressure exerted on the duodenum by the dilated stomach is an important factor in the production of obstructive symptoms. The compression must of necessity be greater before the abdominal cavity is opened, owing to the resistance and counter-pressure exercised by the abdominal muscles. For this reason experiments on the cadaver with the stomach exposed only reproduce in an imperfect manner the conditions present during life. Beyond reiterating the importance of combining lavage with the prone position we have nothing to add as regards treatment.

CASE 1. *Diabetes mellitus: acutely dilated stomach exercising pressure on subjacent duodenum.*—The patient, a male, aged 54, was admitted to St. Thomas's Hospital, under the care of Dr. T. D. Acland, for diabetes. He was previously in the army, gave a history of gonorrhœa but not of syphilis, and had indulged in alcohol. For 18 months there had been steady loss of flesh with polyuria. Latterly swelling of the feet and ankles had supervened. Examination showed an emphysematous chest, no cardiac murmurs, a large amount of sugar in the urine, and also a trace of albumin. After being in hospital six weeks the patient developed slight pyrexia and became very constipated. An acetone reaction appeared in the urine, abdominal pain was complained of, and vomiting, first of brownish fluid and then of bilious matter, set in. Coma supervened and after 12 hours culminated in death.

Necropsy.—This was performed by Dr. W. S. Colman. There was a strong odour of acetone in the body. The pancreas was wasted. The urinary bladder and ureters were dilated, and intense cystitis was present. The kidneys contained foci of suppuration. The stomach was acutely dilated. The gastric dilatation was evidently maintained by pressure of the stomach on the duodenum, since, on raising the former, gas immediately rushed into the jejunum.

CASE 2. *Fractured femur; operation; acute dilatation of stomach with pressure on the duodenum.*—The patient, a male, aged 31, was admitted to St. Thomas's Hospital, under Mr. G. H. Makins, for a fracture of the femur. At the age of 23 he had a "stroke," and the femur of the paralysed leg had been recently fractured below the lesser trochanter in consequence of a fall. The fracture was exposed and united by screws The patient died nine days later. There is no information as to vomiting, but the notes lead to the inference that either general peritonitis or intestinal obstruction was suspected just before death.

Necropsy.—Old tuberculous lesions were found at the lung apices, with a recent outcrop of miliary tubercles in their neighbourhood. The stomach was enormously dilated and crotchet-shaped, its lower border reaching the level of the anterior superior iliac spines. The diaphragm was pushed up to the level of the third ribs. The gastric contents consisted of gas and grass-green fluid. Duodenal distension was traced a little beyond the point where the root of the mesentery lay across it. The coils of small intestine were displaced into the pelvis and collapsed. The body having been in the cold chamber the mesenteric tissues were half-frozen and stiff, so the extent of the duodenal distension could be determined accurately. There was no peritonitis.

CASE 3. *Osteo-periostitis of left femur; suppurative pericarditis treated by incision; acute dilatation of the stomach with pressure obstruction of the duodenum.*—The patient, a girl, aged 17, was admitted to St. Thomas's Hospital, under the care of Mr. H. B. Robinson, for a subperiosteal abscess of the left femur in its lower third. The abscess, which contained the staphylococcus aureus, was treated by incision. Three days later the patient developed pericarditis. The pericardium was drained by removal of the sixth left costal cartilage. A vaccine was also administered. Progress was at first very satisfactory, but between five and six days after admission the patient succumbed, after vomiting profusely for a whole day.

Necropsy.—A circumscribed osteo-periostitis of the lower end of the left femur was found post mortem. The knee-joint had escaped infection. The pericardial cavity was obliterated, its walls being lightly adherent; but there was a recent acute pleurisy with effusion on the left side. The right lung contained a small suppurating infarct The stomach was acutely dilated. It was tense, vertical, and crotchet-shaped. The lower border reached the level of the anterior superior spines. The dilatation involved the duodenum down to the transverse portion, part of the latter only being implicated. The duodenal obstruction was not due to mesenteric traction, since the stomach had displaced the contracted coils of small intestine into the right flank, and not into the pelvis as ordinarily occurs. Raising the root of the mesentery had no influence on the duodenal obstruction, but immediately the stomach was lifted the gastric contents passed into and distended the jejunum.

CASE 4. *Partial resection of colon for carcinoma; acute dilatation of the stomach; flattening of the duodenum by pressure of the overlying stomach.*—The patient, a male, aged 38, was admitted to St. Thomas's Hospital, under the care of Mr. E. M. Corner, for a malignant disease of the bowel. This necessitated excision of the lower part of the ileum, the cæcum, and ascending colon. An end-to-end anastomosis was effected between the dilated ileum and the contracted transverse colon. After the operation the patient vomited profusely. He was treated by gastric lavage and saline infusion, but died on the tenth day. The growth removed was a columnar-celled carcinoma.

Necropsy.—There was a sticky, localised peritonitis around the anastomosis. The stomach, which was greatly dilated, was crotchet-shaped. Its lower border reached lower than the line joining the anterior superior iliac spines. The transverse and terminal ascending portions of the duodenum were flattened by pressure of the overlying stomach. The small bowel was contracted, its coils lying in or near the pelvis. The mesentery was prolapsed, but did not exercise sufficient pressure on the transverse part of the duodenum to prevent the gastric contents passing by on moderate compression of the stomach. The stomach contained a mixture of thick green fluid and gas. Hypostatic pneumonia was found at the left lung base.

CASE 5. *Syphilitic hemiplegia; acute dilatation of stomach; compression of duodenum by mesenteric traction and by weight of stomach.*—The patient, a male, aged 29, was admitted to St. Thomas' Hospital under the care of Dr. H. G. Turney for a recent hemiplegia which had been preceded by headache, sleeplessness, and irritability. The first paralytic symptoms occurred 14 days before admission, but they became aggravated and more widespread 13 days later. Syphilitic infection had occurred seven years before. The Wassermann reaction was positive for the blood, negative for the cerebro-spinal fluid, but the latter showed a lymphocytosis. The patient was treated with full doses of mercury and iodide. After being under observation for a month abdominal pain set in. There was profuse vomiting of dark green fluid with increasing abdominal distension, which, however, did not involve the right flank. Dilatation of the stomach was recognised and lavage resorted to. Eserine salicylate was also injected in quantities of 1/40 grain hourly for three doses. For three days preceding death no action of the bowels occurred.

Necropsy.—The right middle cerebral artery was thrombosed, and softening was found in its area of distribution. The other cerebral arteries were healthy. Gummata and gummatous scars were present in the liver. The kidneys were much enlarged, congested, and their capsules adherent. The heart was hypertrophied, but free from valve lesions. The lungs were œdematous. The stomach was greatly dilated. It lay vertically and had the crotchet outline. Its lower rounded border reached almost to the pelvis. The duodenum was dilated as far as the root of the mesentery. When the latter was severed the transverse duodenum filled out, but the gastric contents did not pass into the jejunum until the weight of the stomach was raised from the side of the vertebral column. The stomach contained a quantity of bilious fluid. The small intestine was contracted and empty.

CASE 6. *Poisoning with vapo-cresoline; acute dilatation of stomach; obstruction of duodenum by mesenteric traction.*—The patient, a woman, aged 43, was found unconscious with a partly emptied bottle of vapo-cresoline by her side. About five drachms of the fluid were missing. (Vapo-cresoline is a clear, translucent, light-yellow fluid, smelling of creasote.) The patient was admitted to St. Thomas's Hospital under Dr. Hector Mackenzie in a condition of extreme collapse, with cold and cyanosed extremities. The pupils were equal and active. No corrosion of mouth or fauces could be detected. The urine, of sp. gr. 1030, was of a dirty brown colour and contained a trace of albumin. The stomach was washed out. Next day the temperature rose from subnormal to 101° F. and signs of broncho-pneumonia appeared. The patient collapsed and died after the administration of an enema.

Necropsy.—There were no signs of corrosive poisoning externally or in the mouth, fauces, pharynx, or œsophagus. A tough membranous pellicle was found in the lower part of the trachea and extended into the main bronchi of each lung. There were signs of intense bronchitis with, near the root of the right lung, some irregular islets of broncho-pneumonia. All the bronchioles were full of tenacious yellow muco-pus. The stomach was acutely dilated and vertical in position. The lesser curvature showed the usual sharp bend and the lower end reached the level of the upper iliac spines. The duodenum was distended to the point where the superior mesenteric vessels crossed it, but here the distension abruptly ceased. The small intestines were entirely collapsed and dragging on the mesentery. On section of the mesenteric root the duodenum and jejunum at once became inflated. The stomach contained a little gas. The interior of the stomach, duodenum, jejunum, and ileum showed no corrosion. The other viscera were healthy.

ON THE OCCURRENCE OF GENERAL SUBCUTANEOUS NON-RENAL ŒDEMA AS A FAMILIAL AFFECTION.

BY F. H. EDGEWORTH, M.D. CANTAB., D.SC. LOND.,
PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY AND PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BRISTOL.

SOME three and a half years ago I came across the case of a baby suffering from general subcutaneous œdema, which was not due to any change in the kidneys, and found on inquiry that three other children had suffered in a like way. I have kept in touch with the family since then, and am also able to record the histories of two later-born children.

The father and the mother are healthy, and, as far as they know, no similar events have occurred in either of their families. All the children were born at full time and were apparently healthy, and they were breast-fed. The first-born, a male, remained quite well until six weeks old, then had a little diarrhœa and became somewhat suddenly swollen all over, and died at the age of seven weeks. The mother then had a miscarriage, at the end of the second month of pregnancy. The second child, a female, began to have diarrhœa when one week old, swelled all over when two weeks old, and died at the age of nine weeks with convulsions. Dr. G. S. Page, who attended this child, has kindly informed me that he tested the urine and found it normal. The third child, a male, had a little diarrhœa toward the end of the third month, then swelled all over, and died at the age of five months.

The fourth child, a male, was quite well until one month old, then had diarrhœa and a fortnight later œdema, first in the left hand, then in the face, and subsequently over the rest of the body. It was admitted to the Bristol Royal Infirmary under my care on Nov. 20th, 1907, aged 9 weeks. The skin was of normal colour and was universally swollen by an œdema which could be easily pitted by the pressure of a finger to the depth of from one-fourth to one-third of an inch. The chest and abdomen were normal. The urine contained neither albumin nor casts. The temperature was normal. The motions were green in colour and fluid. The coagulation-time of the blood, as measured by Wright's tubes, was between 10 and 12 minutes. Two grains of calcium lactate were given three times a day. On Nov. 30th—i.e., ten days later—the coagulation-time was diminished to between 5 and 5¼ minutes and the œdema was less. The child died seven days later without any fresh symptoms or physical signs occurring. At the post-mortem examination by Dr. J. J. S. Lucas no pathological changes were found. The heart, lungs, liver, spleen, kidneys, and alimentary canal were normal.

The fifth child, a male, is now aged 2½ years, and is healthy. During the second and third months of his life he had a slight diarrhœa and œdema of the face, but not of other parts of the body.

The sixth child, a female, was healthy until the age of 3 months, when she began to suffer from slight diarrhœa. I saw her for the first time on March 9th, 1911, when she was aged 3½ months, and could not detect any œdema or other abnormal physical phenomena. On March 12th she had œdema round the left eye, but this had disappeared the next day. Investigation of the fæces by Professor Walker Hall showed a small quantity of unreduced bile pigment, bacillus coli, streptococcus brevis, and staphylococcus—the two latter in slight excess; no bacillus pyocyaneus or Morgan's bacillus. None of the organisms developed pigment on culture. The child was given hyd. c. creta (½ gr. ter die). On March 30th the mother reported that the motions still contained mucus and were green and fluid, though occasionally normal. Œdema round the left eye was again present. The child was taken into the Infirmary on April 3rd; she then had œdema of both legs, and four subcutaneous ecchymoses on the left knee, back, and right arm. The heart, lungs, and abdomen were normal. The urine contained neither casts nor albumin. On April 10th the œdema affected both legs, both hands, and round the left eye. There was slight diarrhœa with green motions. On April 15th the temperature suddenly rose to 102° F., the pulse from 120 to 168, and the respirations from 28 to 64; the œdema rapidly became general; vomiting occurred and continued, and the child died in 12 hours.

At the post-mortem examination by Professor Walker Hall it was found that the heart was normal; in the base of the left lung was a small area of suppuration, containing masses of Gram-positive staphylococci; the spleen was congested; the liver showed widespread deposits of fat chiefly distributed in the peripheral parts of the lobules. In the kidneys the tubular cells showed patches of cloudy swelling; the interstitial tissue was not increased nor distended with serous fluid. In the intestine the lymphoid areas were swollen and slightly congested.

Thus, six children born to healthy parents developed a subcutaneous œdema at ages varying from 1 to 15 weeks. In one case it was slight and confined to the face, and the child recovered; in the other five, death ensued after a period of from 1 to 16 weeks. In three, at least, of the cases no albumin was present in the urine. In the two cases examined post mortem no evidence of nephritis was found.

The cases differ in many particulars from those of the disease named "œdema neonatorum." In that complaint the œdema begins within a day or two of birth, and generally in the lower limbs; the œdematous areas pit with difficulty, and the skin may be tense and shiny. The temperature is subnormal, the pulse slow, there is much drowsiness, and the feeble, often prematurely born, infant dies within 2 to 12 days of birth. It is clear that the above-described cases do not fall within the category of "œdema neonatorum."

All the cases suffered from a more or less marked diarrhœa, shown by green liquid motions before, in some instances only a few hours before, the occurrence of the dropsy. The green colour, in cases of infantile diarrhœa, may be due, though rarely, to pigment-forming micro-organisms, but is more usually due to unaltered bile pigment, owing to the increased rate of passage of food residues through the alimentary canal. This latter cause was certainly true of one of the cases and probably so in all. The children thus suffered from an intestinal catarrh and the dropsy was a related phenomenon.

It is well known that dropsy, especially of the face and extremities, may occur in infants suffering from chronic diarrhœa without albuminuria. The above cases resemble those, though differing in that the dropsy appeared within a few hours or days of the commencement of the diarrhœa.

Clinical observation has shown that albuminuria may occur without any œdema, and, conversely, that œdema may occur without albuminuria. Comparatively recent investigations of those cases in which both albuminuria and œdema occur have disclosed the fact that the occurrence of œdema is often intimately bound up with the amount of certain salts

in the blood and with the capacity of the kidneys to excrete them. Thus if the power of the renal epithelium to excrete chlorides is lessened they accumulate in the blood, raising its osmotic pressure so that œdema occurs; and similarly as regards phosphates. The excretory capacity of the kidneys varies and is independent of its permeability to the proteids of the blood. It is accordingly possible for albuminuria to occur without œdema, and for an œdema of renal origin to occur without albuminuria.

But it appears doubtful whether all cases of general œdema without albuminuria—the so-called "essential" or "idiopathic" œdema—should be referred to a diminished capacity of the kidneys to excrete salts. The œdema in the above-described cases, for instance, may have originated in quite a different way—it may have been due to damage to the walls of capillary blood-vessels by poisons absorbed from the alimentary canal without the occurrence of any change in the excretory capacity of the kidneys. Thus in one of the cases it was found that the administration of calcium chloride diminished the œdema. This is probably related to the fact discovered by Wright that calcium salts diminish, while sodium citrate increases, the rate of osmosis of blood plasma through capillary walls in an inflammatory focus where poisons produced by micro-organisms have damaged those walls. A similar event may perhaps ensue where poisons are produced in distant parts—e.g., are absorbed from the alimentary canal. In support of this explanation of the diminution of the œdema by the administration of calcium chloride, I may adduce the fact—which I have found by experiment—that calcium salts, both lactate and chloride, have no influence on diuresis either in healthy individuals or in those suffering from Bright's disease.

Meyer[1] found, in a case of idiopathic dropsy occurring in an infant, that the daily addition of from 1 to 2 grammes of common salt, or of phosphates, to the diet brought about an increased degree of the dropsy. These results may have been due to the increased salt content of the blood increasing the rate of osmosis through damaged capillary walls, and not be related to any diminished excretory capacity of the kidneys, as was thought. General œdema occurring in cases of infantile diarrhœa may thus be due to a direct action of absorbed poisons on capillary walls. This suggestion would bring such cases into relationship with those of "toxic" œdema produced by certain articles of diet (e.g., shellfish) or by drugs (e.g., potassium iodide), and with those of urticaria of intestinal origin.

It may be doubted, however, whether this is the whole story; the occurrence of "intestinal" dropsy in six successive children suggests the possibility of an inborn defect in the walls of capillary blood-vessels whereby they may be more susceptible to poisons circulating in the blood than are the capillaries of normal individuals. This idea was so impressed on my mind by the history of the first four children that, three and a half years ago, I felt bound to tell the mother that I feared that any children who might be born in the future would probably suffer from dropsy if they had the slightest diarrhœa—a prognosis only too unhappily fulfilled.

If the possibility of inborn variations in the permeability of capillary walls, and in their liability to damage by circulating poisons, were admitted, it would afford an explanation of those cases of general dropsy of the fœtus where no anatomical defects in the placenta and fœtal organs are present, of the cases of hereditary trophœdema (Milroy's disease), of the susceptibility of certain individuals to erythemata and urticaria on the slightest toxæmia, as well as of the lamentable history of the children which I have recorded.

Clifton, Bristol.

UNIVERSITY OF MANCHESTER.—The following appointments have been made:—Lecturer in vegetable physiology and demonstrator in botany: Mr. D. Thoday. Mr. Thoday takes the place of Mr. A. Malins Smith, who has resigned on his election to the position of Principal in the Agricultural College, Chelmsford. Lecturer in orthopædic surgery: Mr. Charles Roberts. Assistant lecturers in surgery: Mr. P. R. Wrigley and Mr. Garnett Wright.

SARCOMA OF THE PENIS.[1]

BY HUGH M. GALT, B.Sc., M.B. GLASG., D.P.H. CAMB., F.R.F.P.S. GLASG.,

PATHOLOGIST, STEPHEN RALLI MEMORIAL LABORATORY, ROYAL SUSSEX COUNTY HOSPITAL; LATE PATHOLOGIST, GLASGOW ROYAL INFIRMARY.

ALTHOUGH not unknown, true sarcoma of the penis is an extremely rare condition. If out of the recorded cases we exclude small melanotic tumours (usually near the meatus) and those which may be termed doubtful from want of specification, the number falls still lower; though it must be admitted, on the other hand, that some cases which have been looked upon as carcinoma of the penis may really have been sarcoma. Most of the text-books decline to commit themselves on the subject of sarcoma affecting the penis, and content themselves either by omitting reference to this altogether, as in Beattie and Dickson[2] and Coats,[3] or by stating that sarcoma occurs, but is rare. Actual specimens of sarcoma of the penis are very few in number in the pathological museums of this country, including Scotland; most of the large museums (including that of the Royal College of Surgeons in London) have none.

Clinically, the diagnosis may be exceedingly difficult, if not impossible. In the instance about to be recorded there was no doubt in the mind of the surgeon that the condition was carcinoma of the penis. In this connexion it is interesting to note that Kaufmann,[4] who terms sarcoma of the penis an example of endothelioma vasculare, points out that the condition is very liable to be confounded with urethral carcinoma. Adami[5] corroborates Kaufmann in this matter. In all the references which I have been able to collect there are only two which are to a slight extent parallel with the present one; these are recorded by W. H. Battle[6] and H. W. Webber.[7] A case of sarcoma of the crus penis is also recorded by E. H. Fenwick.[8]

The present case occurred in September, 1910, when a man, aged 60, was admitted to the Royal Sussex County Hospital suffering from a tumour of the penis, which appeared to originate in the prepuce and to have invaded the surrounding tissues for some distance and depth. The growth was of about the size of the fist, and was soft in consistence and hæmorrhagic at parts. The man had first noticed the tumour as a small papule on the dorsum of the penis about eight months previous to admission; its growth had been more rapid recently. On admission small rather firm masses were distinctly felt in both inguinal regions. As the interest of the case is pathological more than clinical, I need only say that the tumour was duly removed on Oct. 1st by Mr. H. N. Fletcher, with the whole of the penis and crura, and sent to me in the ordinary course of events for minute examination. I saw the mass when it arrived at my department, and I had no doubt, judging from the naked-eye appearances, that the diagnosis of carcinoma of the penis was correct. Sections from several parts of the growth were duly made, and when these were examined in the first instance I was not on duty. My assistant, Mr. Warren, who examined the sections, gave a tentative diagnosis of sarcoma, which diagnosis was fully confirmed by me on my return.

The masses in the inguinal regions enlarged rapidly after the operation; they were accordingly removed by Mr. Fletcher on Oct. 21st and sent to me for examination. The masses were found to be partly within and partly external to the glands. My report on the sections made is as follows: "Sections of portions taken from three distinct regions of the mass from one side show in each case a spindle-celled sarcoma, with hæmorrhage and partial necrosis at points. In two of the sections no gland tissue can be made out; but in the third the lymphoid tissue is present, with the sarcomatous area centrally situated." The naked-eye and histological appearances of these masses are interesting in respect that they indicate in this instance a more or less simultaneous

carriage of the growth by the blood-stream and the lymphatics. The patient died on Nov. 21st; unfortunately a necropsy was not obtained. There was little doubt, however, that there were numerous metastatic growths in the abdomen at least.

After the penis with the attached tumour had been carefully hardened for some weeks it was divided mesially, when the condition shown in Fig. 1 was presented. It will be

FIG. 1.

seen that even without microscopic examination the condition is evidently sarcoma. The tumour originates in the corpus cavernosum, extending from immediately behind the glans to rather more than an inch and a half towards the root of the penis. Both corpora cavernosa were almost equally involved. The direction of growth of the tumour is almost entirely outwards, the mass finally coming to present the appearance as shown, where the prepuce appears to be

FIG. 2.

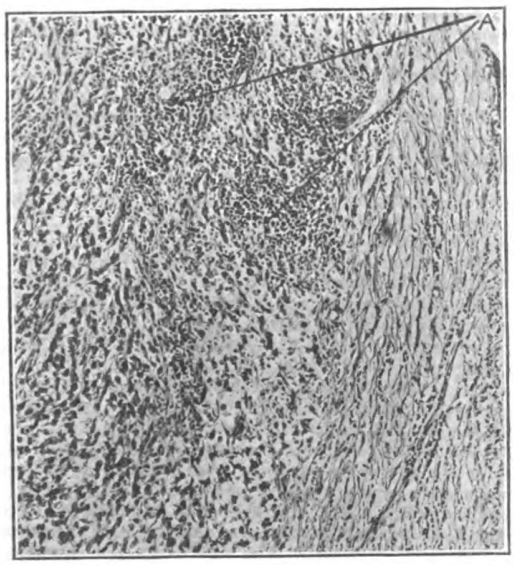

Photo-micrograph of the primary growth. A points to areas of inflammatory deposit. (× 80 diameters.)

the part which is the seat of the tumour. Another interesting feature is that at no time was there the slightest interference with the structure or function of the urethra; the urethral canal is indicated in the figure by a half cylinder of plasticine, showing as a dark rod-like mass. Considering the size of the growth, the limited area of the corpora cavernosa involved is striking.

Fig. 2 shows a photo-micrograph of the primary growth, which was kindly taken for me by Dr. E. J. Spitta. The field selected is near the surface, and shows the stretched and thinned-out epithelium covering the growth, with consequent obliteration of the papillæ. The magnification is 80 diameters. The picture is that of a spindle-celled sarcoma, with the usual interlacing of the bundles. To all appearance there is no stroma whatever. At two parts in the figure there are small aggregations of inflammatory cells; these were entirely absent in the central portions. The appearances in the case of the sections from the inguinal mass were exactly similar, with the addition of hæmorrhage and necrosis at parts, so there was nothing to be gained by having another photograph taken of this secondary deposit.

Alike in the history, course, termination, and histological picture the present case is typical of sarcoma. In most, if not all, of the cases previously recorded there were deviations in some direction. In Webber's recent case, for instance, there was purulent urethral discharge with pain on micturition, and the sections showed "a fibrous tissue network with wide irregular spaces filled with large round and oval cells." In some of the other cases the cells are also described as being round in character. No photographs are given in cases which have been recorded previously.

As to the ultimate origin of the cells from which the growth originated, it is impossible to speak with certainty. They may have arisen from: (1) the endothelium of the vessels of the corpora cavernosa (Kaufmann's endothelioma vasculare); (2) the endothelial lining of the lymphatics of the same structures; and (3) from the connective tissue cells of the inter-sinusoidal stroma. At no part was the epithelium involved in the growth.

It is not at all unlikely that we shall find, as time goes on and the routine histological examination of every piece of tissue removed from the body becomes general, that sarcoma of the penis is not so very rare as present statistics would indicate.[9]

Brighton.

A CASE OF ANTERIOR DISLOCATION OF THE SEMILUNAR CARPAL BONE.

BY W. ROWLEY BRISTOW, M.B., B.S. LOND., F.R.C.S. ENG.

THE patient, aged 48, fell down two stairs on Dec. 13th, 1910, bruising his side, damaging his left wrist, and cutting his head. He was concussed by the fall, and remained unconscious for about three-quarters of an hour. On recovering consciousness he had no notion of the exact method of falling, and did not know whether the wrist was in a position of extension or of flexion. His head condition and bruised side rapidly recovered, but the wrist remained swollen, painful, and with marked limitation of movement. An X ray examination was made, but no fracture was discovered, and the case was regarded as one of a severe sprain of the wrist. Massage and movements were tried, but these caused considerable pain and produced no beneficial result.

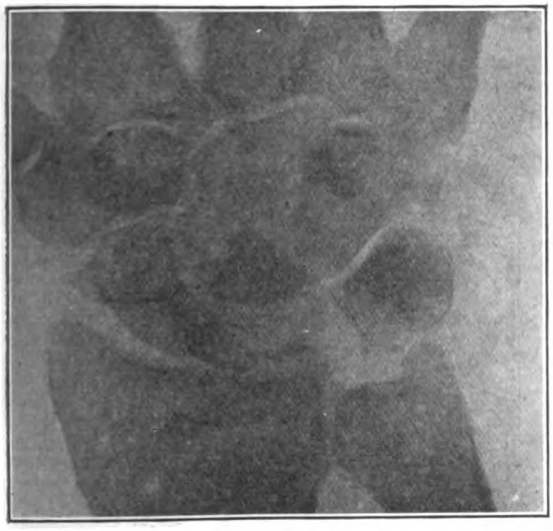
I first saw the patient seven weeks after the accident. The left wrist was thickened, and there was a prominence just on the carpal side of the radio-carpal joint and deep to the flexor tendons. There was well-marked synovitis of the flexor tendon sheaths. This part of the wrist was tender on pressure. The styloid processes of the radius and ulna were normally placed, but the palm appeared to be shortened when compared to that of the opposite side. There was no tenderness or swelling in the anatomical snuff-box to indicate fracture of the scaphoid. The movement at the wrist and mid-carpal joints was markedly restricted. Flexion was almost *nil*, extension was limited to a few degrees of movement, and abduction and adduction of the hand were limited, although to a less extent. On attempting any forcible movement great pain was experienced, and also a tingling of the fingers over the median nerve area. The grip with the left hand was very poor, and there was

[9] Additional references:—Hektoen and Reisman: A Text-book of Pathology, 1901, p. 1012 D.; THE LANCET, March 21st, 1885; Nov. 23rd, 1889 (this refers to Fenwick's case, *ut supra*).

very marked wasting of all the muscles of the forearm. These muscles at once went into spasm on attempting forcible movement of the joint.

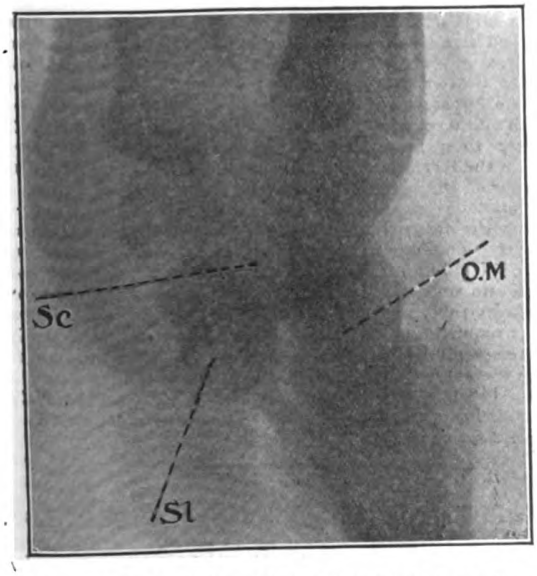
An X ray examination by Dr. A. D. Reid showed clearly an anterior dislocation of the semilunar bone. (Figs. 1 and 2.) There was no fracture of the scaphoid. The position of the displaced semilunar was such that the facet for articulation with the radius looked directly backwards, and the concave facet for the os magnum directly forwards. The head of the scaphoid was partially dislocated forward, superposing the top of the semilunar in the skiagram.

FIG. 1.



Skiagram of antero-posterior view showing displaced semilunar bone.

FIG. 2.

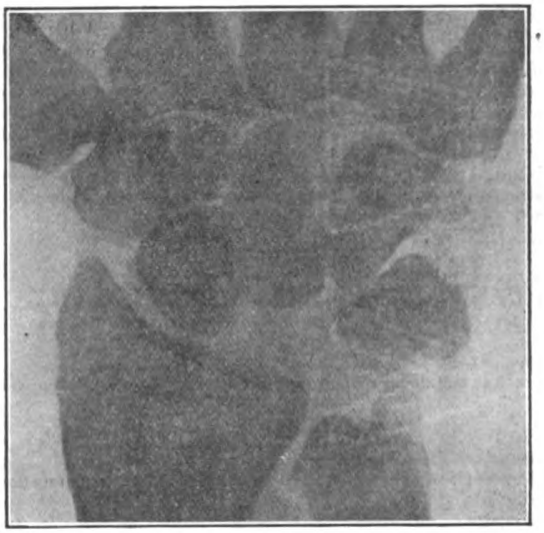


Skiagram of lateral view showing displaced semilunar bone. Sc, Head of scaphoid. Sl, Semilunar. OM, Os magnum.

Treatment.—Operation on Feb. 14th, 1911, under ethyl chloride and ether. Under the anæsthetic no further movement was possible. Attempted reduction was not successful. When the muscles were relaxed under the anæsthetic the obstruction to the joint movement was obviously bony. An incision 2 inches long was made immediately to the ulnar side of the palmaris longus tendon; this tendon and the median nerve were retracted outwards and other flexor tendons inwards. The semilunar bone was found lying between the flexor longus pollicis and the flexor profundus digitorum, with the concave articular facet for the os magnum looking directly forwards—the position which the skiagram had previously shown the bone to occupy. The semilunar had come forward through the capsule of the wrist-joint, which had completely closed behind it. The bone was lying free except for two strong ligaments holding it to the scaphoid on the radial side. These ligaments were divided and the semilunar was excised. The wound was closed with silkworm gut. After the operation the movement at the wrist-joint was quite free, and full flexion was possible. The wrist was bandaged up in a semi-flexed position.

On Feb. 21st the stitches were removed. The wound healed by first intention. The muscles of the forearm were treated by the method of graduated contraction with an

FIG. 3.



Skiagram showing antero-posterior view after excision of semilunar bone.

FIG. 4.

Skiagram showing lateral view after excision of semilunar bone.

induced current[1] instead of by ordinary massage, and the wrist and mid-carpal joints were moved in the same way. The treatment was carried on for six weeks, the amount of movement being gradually increased. The patient resumed his work a fortnight after the bone had been excised. He was last seen on April 19th, when the movement at the joint was excellent; extension, abduction, and adduction were complete. Flexion was almost full, about 70°, showing that both the wrist and mid-carpal joints were functioning. The wrist-joint is strong and the patient is quite able to do anything with the hand, and suffers no ill-effects from the injury.

Remarks.—The dislocation of a single carpal bone is a somewhat rare occurrence. Codman and Chase[2] have collected 12 cases of dislocation of the semilunar bone, and in almost all of these cases there has been fracture of the scaphoid as well. In the only two cases in which this dislocation occurred, and in which the scaphoid was intact, the radius or ulna was fractured. In the present case, although a series of photographs and stereoscopic views were taken, there was no sign of fracture of the scaphoid or of the radius or ulna.

Harley street, W.

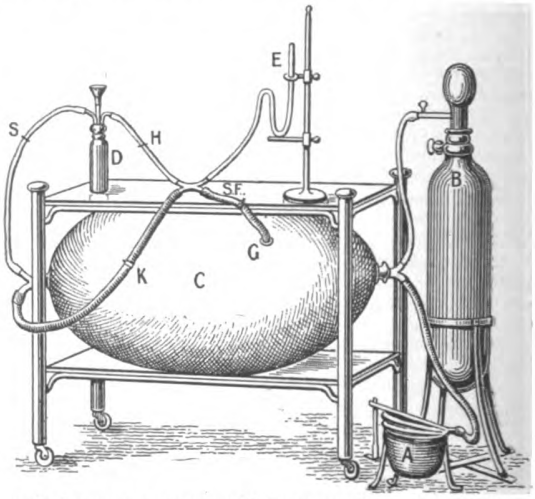
A CASE OF PLUS-PRESSURE ANÆSTHESIA FOR EXPLORATORY THORACOTOMY.

BY F. HERBERT WALLACE, F.R.C.S. EDIN.,
LATE SENIOR ANÆSTHETIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

THE following case will, I think, prove of interest to readers of THE LANCET.

The patient, aged 23 years, was suffering from non-malignant stricture of the œsophagus. For the purpose of performing an exploratory thoracotomy anæsthesia was brought about by ethyl-chloride followed by $CHCl_3$. A Skinner mask was first tried, but as there was some difficulty in retaining the tracheal tube in position tracheotomy was performed and a full-size Durham's tube was inserted and the anæsthetic administered through the tracheotomy tube by using the Junker's apparatus without any increased pressure, respiration taking place through the free tube. As soon as the pleural cavity was opened, 30 minutes after the commencement of the anæsthetic, the free air-way was gradually closed up, and air under pressure of 15 mm. of mercury was forced into the trachea. This pressure was found to be sufficient to keep the lungs distended well up to the thoracic wall. There was a certain amount of leakage about the tracheotomy wound and into the pharynx. The manometer registered 10 mm. of mercury at inspiration and 15 mm. at expiration. Continuous pressure was used. A corneal reflex was kept throughout the whole time of operation. The patient's pulse at the commencement of the increased pressure was 80 beats per minute, regular, and of good volume, the respirations being 18 per minute. The use of a lung retractor and manipulation caused the upper lobe to collapse, but this was quickly overcome when retraction ceased. After 15 minutes of pressure the leakage became more pronounced, and a face-piece was added to overcome the escape through the nose and mouth. After 25 minutes the patient began to get slightly cyanosed; the pulse-rate had increased, and the respirations were now 24 a minute. Oxygen was allowed to run into the bag, and this successfully combated the cyanosis. The regular movement of the diaphragm never ceased the whole time. The patient's pulse was getting more rapid and somewhat collapsible, 96 beats a minute. An injection of pituitary extract was given—10 c.c. of a 20 per cent. solution; this considerably improved the volume, but did not lessen the number of beats. The upper lobe towards the end of the operation did not move so well as at first and appeared to be œdematous, but the lower lobe was not so affected. The lung, however, distended well into the wound. While the thorax was open the pulse-rate never reached 100 beats a minute, but did so during the closing of the wound. At the finish of the operation, an hour and 15 minutes from the commencement of the anæsthetic, the patient had a good colour and the pulse was about 112, regular, and of good volume. There was, however, as indicated by the pulse, severe shock in spite of special precautions taken both before and during the operation. The wound was closed as accurately as possible and an attempt was made to render it air-tight. Pressure was kept up until the dressings were on. Three drachms of chloroform were used and 5 cubic feet of oxygen. The patient came round from the anæsthetic when the bandages were being adjusted. I will briefly describe the apparatus used.

A foot-pump and cylinder of oxygen are coupled to a large and stout rubber gas-bag. A V-shaped junction then carries a Junker's apparatus on one arm, and the other links up again



A, Foot pump; B, oxygen cylinder; C, gas bag; D, Junker's inhaler; E, manometer; F, air-way; H, valve; G, delivery tube; S, screw regulating clips; K, spring clip. Dark tubing, ½-inch rubber; light tubing, ¼-inch rubber.

with the efferent tube of the Junker. A manometer is also in the air-way and a free opening close to the delivery tube. Spring clips are placed on the air-way and the manometer tube and screw regulator clips on the afferent Junker tube and free air-way. A valve is in the efferent Junker tube to prevent the plus-pressure blowing the chloroform into the apparatus. The main tubing is half an inch and the Junker a quarter of an inch in diameter. The delivery tube may be either inserted into the trachea through the larynx and should be about three-quarters of the diameter of the trachea, or fitted in a tracheotomy tube. A mask may be used on the face with no outlet, in order to prevent the fall of air pressure through leakage into the pharynx. Pressure is obtained by the foot pump, and the amount of chloroform is regulated by the screw-clips. There is a certain amount of leakage round the tracheotomy wound or delivery tube, and the free tube should be slowly closed till the requisite pressure is obtained by manometer, or, what is more essential, till the lungs expand well up to the opening in the thoracic wall.

I am indebted to Mr. Edward Gillespie and to Mr. Walter Edmunds for permission to publish the notes of this case.

Upper Clapton-road, N.E.

INFARCT OF THE TRANSVERSE COLON.

BY H. T. GILLETT, M.D. LOND.

CASES of infarct of the large bowel are so rare that the following is worth placing on record.

The patient, a woman, aged 49 years, had been troubled with piles for some time, but was otherwise well, till she woke in the night of Dec. 18th, 1910, with severe sense of pain in the epigastrium and flatulence. She blamed the cocoa she had had for supper. On the 19th diarrhœa began and the pain in the abdomen increased. On the 20th the diarrhœa continued and there was nausea. Blood in the stools was first noticed in the afternoon. During the following night she had two actions of the bowels; both were practically pure blood, bright in colour, and only very little

fæcal matter (perhaps half an ounce in weight). Some clots were present of the size of half a hazel-nut—about five ounces of blood in each stool. Dr. William Collier saw the patient on this date. On the 21st there was more nausea; the abdomen was not distended. The pain was mostly below the navel and right across the abdomen; there was slight rigidity all over. The pulse and temperature were normal. On the 22nd an enema of olive oil was retained. Two actions followed: (1) charged with blood and fæcal matter; and (2) no blood, but pultaceous fæcal matter. On the 23rd the abdomen was a little distended and there was more nausea. The temperature on the previous night was 99° F. The pulse rose to 84. Professor Osler saw the patient on this date. A distinct thickening could be made out between the navel and the ensiform cartilage; it was tender and moved slightly on respiration. Mr. A. P. Dodds-Parker operated in the afternoon. The transverse colon for the greater part of its extent was of a dark purple colour; the walls were greatly thickened. It did not look gangrenous. The ascending colon was anastomosed to the lower part of the descending colon. The patient did well for the first 12 hours. Then she had tetanic spasms, which continued at intervals of a few minutes for nearly 12 hours. She died late in the afternoon of the 24th.

A post-mortem examination was performed by Dr. A. G. Gibson. The transverse colon was of a dark purple colour; the walls were greatly thickened and the lumen was much reduced. There were minute hæmorrhages in the walls, which were microscopically shown to be in a condition of infarct. The branches of the colica media were empty; no emboli were found; there was no peritonitis, but there were hæmorrhages in the transverse meso-colon. There was a small amount of blood-stained fluid in the peritoneal cavity. Microscopic examination of the mesenteric arteries did not show any sclerotic changes. There was an old mitral lesion, with some narrowing of the orifice, and a few vegetations on the edges of the valve.

Infarct of the intestines is comparatively rare. Gallavardin[1] collected 83 cases; of these, 63 were embolic. Jackson, Porter, and Quimby collected 214 cases of infarct, including both thrombotic and embolic cases. Of these, 64 per cent. were men; 47 were operated upon and only 4 recovered. In one case (Elliot's) that recovered 48 inches of the bowel were resected. In the case now recorded the short-circuiting of the bowel was successful, but death took place as a result of toxic poisoning. Possibly resection might have prevented this if the patient had been strong enough to stand the operation.

Osler and McCrae say that the mesentery may be greatly thickened, a veritable hæmatoma. In the above case there was only a little extravasation of blood and no thickening in the mesentery. Kemp[2] says that occlusion of the smaller branches of the superior mesenteric causes embolic or thrombotic ulcers of the intestines, and there may be lesions scattered in several places over the bowel with healthy segments between them, but occlusion of a larger vessel usually involves a continuous segment of the gut, quite frequently in the lower jejunum and ileum.

Two types of cases have been described by Kussmaul and Gerhardt.[3] 1. Sudden abdominal pain followed by nausea or vomiting and also diarrhœa, which is at first mucous and watery and at last bloody. Gerhardt states that the blood is bright red when the inferior mesenteric is obstructed, but that in obstruction of the superior vessel it is darker. Kemp states that it is generally dark. In the present case it was bright red in the actions on the third day of the illness. 2. The second type of case simulates acute intestinal obstruction, with distended painful abdomen and sometimes fæculent vomiting. Apparently this case illustrates the first type, though signs of obstruction showed themselves before operation was resorted to.

The mortality is very high, 92 per cent. in Jackson, Porter, and Quimby's cases. Death occurs within three days as a rule; the longer duration, six days in this case, may have been because the colon was affected and the obstruction was not complete.

I am indebted to Sir William Osler for his help and suggestions in recording this case.

CASES OF (1) CHRONIC PANCREATITIS, AND (2) CARCINOMA OF THE PANCREAS.

BY G. Y. THOMSON, M.B., B.S. LOND.,
HOUSE SURGEON, GUY'S HOSPITAL.

Mr. R. P. Rowlands has kindly permitted me to publish the following consecutive cases with remarks by him on the diagnosis. There are six cases altogether, of which the first three are cases of chronic pancreatitis and the last three of carcinoma of the pancreas. The former have done very well; the latter have died, one on the third day and the other two about four months after the operation and nine months from the onset of jaundice. In Mayo Robson's and Cammidge's text-book altogether 49 cases are quoted; of these, 39 are cases of chronic pancreatitis, with two deaths, not in any way connected with the operation, and ten cases of carcinoma of the pancreas with seven recorded deaths. The following important points may be gathered from a careful consideration of these cases: (1) The results of cholecystenterostomy in cases of chronic interstitial pancreatitis compressing the bile-duct are excellent; (2) the difficulty of diagnosis between the two conditions even when a laparotomy is performed, and hence the advisability of cholecystenterostomy in doubtful cases; (3) the mortality in cases of carcinoma, though temporary relief may be afforded by operation.

Chronic Pancreatitis.

CASE 1.—A man, aged 35, admitted on Feb. 16th, 1908, for pain in the upper part of the abdomen on the right side and jaundice. For two months he had suffered a good deal from indigestion and pain about the epigastrium and gall-bladder region, often vomited soon after meals, and occasionally had diarrhœa, and soon became jaundiced; the stools became light-coloured and the urine very dark. On admission the jaundice was a little better, but attacks of pain were very severe, being only relieved by morphia. The pain was above and a little to the right of the umbilicus, extending straight through to the back; the patient did not become pale and there was no sickness during the attack. The upper part of the abdomen was tender and rigid, especially to the right of the mid-line; the gall-bladder was palpable. By Feb. 19th the jaundice was worse again, attacks of pain more severe, and the patient was wasting rapidly. Exploration was advised.

Operation.—The abdomen was opened through the upper part of the right rectus. The gall-bladder was found to be enlarged. No stones were felt in it or in any of the bile-ducts, or at the common opening o the common bile and pancreatic ducts into the duodenum. The head of the pancreas was enlarged and hard, and was thought to be carcinomatous. A small piece which was removed only showed inflamed pancreas. No stones were felt on palpating the pancreas. Anastomosis was made between the fundus of the gall-bladder and jejunum about 9 inches from the duodenal and jejunal flexure; suturing was direct with the aid of clamps. The opening was made as large as possible, and three layers of sutures were used. The abdomen was completely closed.

Recovery was uninterrupted, the patient never had another attack of pain, and the jaundice soon disappeared; he rapidly gained weight and left hospital on March 13th. Since then he has worked constantly. On May 10th, 1910, he was seen looking and feeling well. There had been no pain nor indigestion since the operation.

CASE 2.—A woman, aged 34, admitted on March 3rd, 1908, had 18 months before felt very ill; no diagnosis was made, although typhoid fever and influenza were suggested. Seven weeks before admission she had a feverish attack lasting three weeks; there had been a good deal of fever, a purpuric rash all over the body, a great deal of abdominal pain, also two rigors and pains in the limbs; a diagnosis of influenza was made. Soon afterwards she had a good deal of pain on the right side and she became jaundiced; the pain got more severe and the jaundice got deeper and deeper. On admission she was deeply jaundiced and thin. She had attacks of severe pain in the upper and right part of the abdomen; gall-bladder was palpable; there was a great deal of tenderness and rigidity just above the umbilicus. A diagnosis was made of obstruction of the common bile-duct, due probably to stone.

Operation.—The abdomen was opened through the upper part of the right rectus. The gall-bladder was distended, but no stone was found in the biliary apparatus. The head of the pancreas was considerably enlarged and hard, and no stone could be felt about the pancreatic duct or duodenal papilla. Anastomosis was made between the fundus of the gall-bladder and jejunum. There was a good deal of oozing of blood during the operation; therefore a tube was placed in the right kidney pouch for drainage. The patient did well for a few days, but three weeks later a subdiaphragmatic collection of sterile blood was drained, after which she rapidly recovered and left hospital well on May 10th.

CASE 3.—A man, aged 40 years, was admitted on May 24th, 1909, for deep and persistent jaundice of five weeks' duration. He had served in the army for 13 years, and thought he had syphilis in India in 1896; he had a slight attack of dysentery during the South African war. He had vomited nearly every morning for two years, but otherwise had been in good health until April 20th. On the following day he felt ill and gradually became jaundiced. A medical man on April 21st treated him with mercury and potassium iodide. On admission he was jaundiced and the liver was enlarged; he had no pain. Gradually the jaundice became deeper, until it was greenish-black, and he gradually lost flesh, also suffering a good deal from itching of the skin. The gall-bladder could be felt, and there was a vague swelling and tenderness just above the umbilicus in the mid-line. The temperature was

never raised above normal. A diagnosis of syphiloma or growth of the pancreas was made and an exploration was advised.

Operation.—On July 20th the abdomen was opened and the biliary apparatus examined in the usual way; no stone was discovered. The gall-bladder was enlarged and distended; the head of the pancreas was enlarged, hard, and fixed; another distinct and hard enlargement was found near the tail of the pancreas—these were considered to be malignant. The liver was considerably enlarged, but no growth was seen or felt in it. Cholecyst-jejunostomy was performed; the limbs of the jejunal loop sagged, thus tending to produce kink; each was held np by a suture passed through the capsule of the liver. The abdomen was completely closed, and the patient made a rapid and complete recovery. He is now in perfect health and doing heavy work.

Carcinoma of the Pancreas.

CASE 4.—A man, aged 41, who weighed 13½ st. until July, 1910. He thought he had indigestion early in July and after a week or two jaundice appeared. He had a similar attack five weeks before the date of consultation (Dec. 8th, 1910), with discomfort high in the epigastrium, nausea, anorexia, but was not sick. He had had two attacks of sickness, one in September after bathing. The patient was said to be subject to migraine. The motions were clay-coloured and had been much lighter lately; the urine had been high-coloured until five weeks ago. There had been no constipation lately. He had worked hard until a week ago. There had been no pain with any of the attacks of migraine. Examination on Dec. 8th: The patient is very thin; he is jaundiced but not deeply; skin dry and rough, tongue furred, some anæmia, arms very dark; motions pale clay-coloured. No rectal or colic growth could be found. An enlarged gall-bladder could be felt under the slightly enlarged liver; no pancreatic swelling could be felt; there was no elevation of liver dulness. The chest was normal.

Operation.—Open ether. The abdomen was opened through the upper part of the rectus, some fibres of which were cut across. A large gall-bladder was at once seen; common duct also dilated; pancreas enlarged, hard, and fairly fixed; no stone could be felt in the common duct. It was thought that the condition of the pancreas was probably due to chronic pancreatitis or possibly to carcinoma of the head of the pancreas. The body of the pancreas was enlarged and some hard nodules were felt along the lower border of it. The liver was slightly enlarged, but no growth could be seen or felt in it, and none could be felt in the portal fissure. It was seen that it was impossible to join the gall-bladder to the duodenum, which was not as moveable as usual. It was therefore decided to join it to the jejunum about 12 inches from the origin. The gall bladder was so distended that it was impossible to get any of it into the clamp. After packing the loin and above the gall-bladder, the patient was turned on his right side and the gall-bladder was opened, allowing a large amount of bile to escape. Clamps were then applied above the jejunum and gall-bladder, whilst a large opening was made in each of them, and anastomosis was made by means of Pachenstecher's thread reinforced with several interrupted sutures of the same material. The packing was then removed and the parts were cleaned. The abdomen was closed, catgut being used for the peritoneum and salmon-gut sutures for the remaining layers. The operation lasted about 35 minutes, and the patient was not much worse at the end of it.

Directly the patient was returned to bed continuous rectal infusion was commenced. He had rather a bad night, vomiting a good deal of brown material, which was clearly altered blood and bile mixed together. Four pints of saline were given per rectum during the night and only water by the mouth. There was some oozing of blood from the wound; this was controlled by putting in another stitch. The temperature was normal; pulse 74; there was no pain. Calcium lactate was given by the mouth and per rectum. Dec. 15th: 10 oz. saline enemata were given every four hours, alternating with nutrient enemata. The patient returned home on Jan. 5th, 1911. The jaundice had not entirely gone, but it was rapidly clearing, especially on the limbs. He had done very well. The weight at the date of the operation was 11 st. 6 lb. When he left the hospital it was 10 st. 5 lb. By Jan. 18th it was 10 st. 11 lb. On March 1st it was 11 st. 3 lb. 8 oz. The patient, however, did not progress satisfactorily; he developed œdema of the legs and ascites, which indicated that he was really suffering from carcinoma of the pancreas. Diarrhœa with oily stools persisted in spite of pankreon in increasing doses. He died on May 11th.

CASE 5.—A married woman, aged 43. The patient had always been fairly healthy, although at times she had suffered from some indigestion, and had had two attacks of influenza. Five months before admission she caught a chill and then became jaundiced. The jaundice had never left her, and she was getting gradually weaker. Since the beginning of the illness she had lost 3 st. in weight. She had had a little pain in the upper part of the abdomen, but it had never worried her very much. The yellow colour had gradually increased in intensity, and there had been considerable irritation of the skin. During her illness the urine had been persistently dark in colour, and the fæces had had a "cement colour." The patient had never suffered from colic pains nor from vomiting.

Operation.—Jan. 7th, 1911. Morphia (¼ gr.) was injected 30 minutes before the anæsthetic. The abdomen was opened through the upper part of the right rectus, some of the fibres being cut across. A greatly distended gall-bladder was seen, and the common duct was also dilated. The pancreas was hard and enlarged as regards the head, neck, and body. No enlarged glands were felt. The pancreas was not fixed to the spine. The liver showed no signs of growth. No stone was felt about the duodenal papilla. A diagnosis of chronic pancreatitis was made, but suspicion of growth remained. No gall-stone was found in the gall-bladder or duct anywhere. The fundus of the gall-bladder was joined to the jejunum 10–12 inches from the duodenum. The kidney pouch was well packed with gauze and the parietal wound was also protected. The patient was turned slightly on her side while the gall-bladder was incised and almost emptied of very thick bile. The gall-bladder was clamped with forceps, the parts cleaned, and anastomosis made between the gall-bladder and jejunum as already mentioned. Two continuous silk sutures were used with a few interrupted reinforcing sutures. The abdomen was closed with catgut for the peritoneum and rectus sheath. The operation was well borne.

During the night the patient vomited a large amount of altered blood and bile. The stomach was washed out early in the morning; this reduced the pulse from 130 to 110. She was better again in the evening, but on the morning of the 9th brought up nearly half a pint of bile. She was better after this until the evening, but was again sick in the evening, bringing up 6 ounces of rather offensive bile and blood; afterwards she rapidly improved. She was given a fair amount of water by the mouth and nutrient and saline per rectum, alternating every four hours, 60 grains of calcium chloride in each nutrient. On the third day the vomiting ceased. The bowels were opened as a result of enema terebinthinæ. On the 10th the patient, who had wasted a great deal, became delirious. The bowels were opened three times later in the day, but this gave no relief. The head and shoulders were lowered in case the delirium was due to cerebral anæmia. She slept fairly well after morphia (1/6 gr.), but the next day was weaker and more stupid, although she took food well and the bowels were acting. The temperature was normal; the abdomen was supple and moved freely. She continued to take liquid nourishment well, and after three days gradually recovered consciousness, and although she had no control of the sphincters for several days she made a rapid recovery and went out of the hospital. Jaundice was then much diminished and the general condition much improved.

The patient, however, did not progress satisfactorily and had ascites and œdema of the legs, which indicated that she was suffering from carcinoma of the pancreas. She also had diarrhœa with oily stools, which was only partly relieved by pankreon. Her abdomen was twice tapped; on one occasion 22½ pints were drawn off. She died on May 18th.

CASE 6.—The patient had had a series of bilious attacks from an early age, but otherwise had enjoyed fairly good health. Seven weeks before admission there was a general feeling of malaise, depression, and loss of energy. This was followed by gradual onset of jaundice, accompanied by dark-coloured, firm, and clay-coloured stools. The patient had occasional attacks of intense pain across the upper part of the abdomen. The pain was of a colicky nature, sometimes causing vomiting. Two stones in weight had been lost during the last eight weeks. The jaundice had been gradually increasing in intensity. Despite careful medical treatment the patient had continued to lose weight, and the jaundice had not got less; hence laparotomy was advised.

Operation.—The gall-bladder was found to be greatly distended. The pancreas was very hard, and two hard lumps were felt on the convex surface of the liver. Cholecystenterostomy was performed in a similar manner to those cases which have been already described. Carcinoma of the pancreas with secondary deposits in liver was diagnosed. The patient died from cardiac failure three days after the operation.

The necropsy showed diffuse carcinoma of the pancreas with small secondary deposits in the liver. The common bile-duct was markedly dilated. No gall-stones were present in the gall-bladder or biliary apparatus.

Causes of pancreatitis.—(1) Ascending infection from duodenum; (2) obstruction of pancreatic or biliary duct by calculi (chronic).

Diagnosis.—1. A history of previous attacks of jaundice associated with colic, or of colic alone, is in favour of gall-stones. A beginning with vague pains in the epigastrium, associated with fever and gradual appearance of jaundice, is in favour of pancreatitis.

2. Impaction of a stone in the common bile-duct is usually associated with severe colicky pain. Pain is especially bad at moment of impaction. The patient is sick and pale, with small feeble pulse, and shivering may occur. No relief is afforded except by morphia or lapse of time. Typical biliary colic is much more sudden and severe than that associated with pancreatic disease, whether inflammatory or malignant. It may fall away as suddenly as it came. It is felt deep in the right side above and to the right of the umbilicus; it extends to the back, and especially towards the right shoulder. The pain associated with pancreatic disease is less violent and unaccompanied by shock, it is lower, and extends to the back lower down and more to the left than that of biliary colic. In some cases impaction of stone in the common bile-duct is not associated with pain; nausea then takes its place.

3. The local tenderness due to impaction of a calculus is usually higher and more to the right than that due to pancreatic disease.

4. The jaundice due to stone is more intermittent than that due to pancreatitis, and especially than that due to growth, which gets progressively deeper. Jaundice due to pancreatitis is rarely so deep as that due to growth, but when chronic pancreatitis has lasted a long time the jaundice may become very deep or even greenish-black, as in one of the cases.

5. Enlargement of the gall-bladder is against gall-stones as a cause of jaundice, although there are exceptions to this rule as to all others.

6. With growth or pancreatitis a vague swelling about the umbilicus is sometimes felt, especially when patient is under an anæsthetic.

7. Severe anæmia and wasting occur in pancreatitis and growth, but not until quite late in jaundice due to stone in the common bile-duct. So severe are the blood changes that many cases of chronic pancreatitis with but slight jaundice have been diagnosed as pernicious anæmia.

8. Diarrhœa, with fatty and fœtid stools containing muscle fibres, is commonly associated with pancreatitis, and

also with carcinoma of the head of the pancreas. A stone impacted at the common opening of the pancreatic and bile-duct may give the same symptoms.

9. Cammidge's reaction is rather complicated for general use, but it should always be tried, as a positive reaction strongly points to inflammation, as against growth.

Guy's Hospital.

FEEDING EXPERIMENTS IN FOWL SPIROCHÆTOSIS.

BY ANDREW BALFOUR, M.D. EDIN., F.R.C.P. EDIN.,
DIRECTOR, WELLCOME TROPICAL RESEARCH LABORATORIES, GORDON COLLEGE, KHARTOUM.

THE natural or artificial infection of animals by pathogenic protozoal parasites viâ the alimentary canal is a subject both interesting and important. It was first given prominence by the lamented Miller,[1] who showed that white rats became infected with Hepatozoon perniciosum by devouring the mites Lelaps echidninus which served as intermediate hosts for that parasite of the mononuclear leucocytes. Recently Strickland[2] has found that rats can be infected with T. lewisi by eating fleas which contain this trypanosome. His conclusions are: (1) Infection of rats with T. lewisi is caused by the rats' act of eating infective fleas; (2) it is not caused by contamination of the rats during a short time, nor by their being bitten by the fleas; (3) many more fleas are infective than cause infection in nature; (4) the infective form of the trypanosome, which is probably the "small trypanosome" of Swellengrebel and Strickland, must reach the blood through the gut-wall; (5) it is possible that other trypanosomiasis may be transmitted by perhaps even non-blood-sucking creatures. Minchin and Thomson[3] criticise these results and state that their experimental results support the belief that the infection of rats with T. lewisi is not brought about normally through the rat eating the flea, but by the infection of the wound made by the proboscis of the flea serving as a place of entry for the ripe infective form of trypanosome—the final developmental form in the flea—which is regurgitated from the insect during the act of feeding.

Turning now to the question of spirochætosis we may note in the first instance that Leishman[4] is inclined to think that in the case of Sp. duttoni and Ornithodoros moubata infection takes place during the act of feeding, not by way of the veneno-salivary secretions, but viâ the wound made by the tick, which becomes bathed in the clear fluid copiously secreted by the tick from its coxal glands, and sometimes also by the white secretion from its Malpighian tubes, these fluids containing developmental forms of the spirochæte derived from the granules which I[5] have shown in the case of the fowl spirochæte are shed by the parasites in the contents of the intestinal sac of its intermediate host—Argas persicus. In all probability this is the way in which man acquires African tick fever, but it is to be noted that, so far as Sp. recurrens is concerned, Gózony[6] has recently shown that it can penetrate the mucous membrane of the intestinal tract in experimental animals. The last author I would quote in this very brief *résumé* is Schellack,[7] who, working with Sp. gallinarum (marchouxi), notes that if the hen-house be infected the birds can acquire spirochætosis per os.

This leads one to the subject of this paper, for I have found that if healthy chicks be fed on ticks (Argas persicus), which themselves have recently fed on birds infected with Sp. granulosa penetrans, the fowl spirochæte of the Soudan, the chicks speedily develop spirochætosis. Not only so, but if healthy chicks be fed on a sufficient number of ticks which, having fed a long time previously on spirochæte-infected birds, harbour, not spirochætes, but granules only, these chicks likewise become infected through the alimentary canal. In both cases the incubation period is short, in one instance it was very short, and it may be said that care was taken to exclude any other possible source of infection as will be evident from the following account of the experiments.

Experiment 1.—May 20th and 21st: A batch of ticks (Argas persicus) was fed for two successive nights on a chick showing a heavy spirochæte infection. Ungorged ticks were rejected and of the gorged a few were taken and their cœlomic fluid and the contents of their intestinal sacs examined by the dark-field method, which proved the existence of numerous living spirochætes in the ticks. May 22nd: A healthy chick, newly brought in from a locality outside Khartoum, where no fowl spirochætosis was known to exist, was placed in a glass jar and given seven of these gorged ticks as food. It devoured them all as they were introduced one by one. A ring of vaseline was placed round the lip of the jar to prevent the access of any ecto-parasites, such as lice, which I have proved can act as vectors of the fowl spirochæte. May 28th: To-day for the first time the bird was found with spirochætes in its blood. The disease ran a fairly severe and rapid course and the bird died, heavily infected, on June 1st.

Experiment 2.—An experiment similar in all respects to the above, with the single exception that the chick employed was carefully examined and cleared of all ecto-parasites, such as lice and mites, before being placed in the jar, was carried out, the feeding with infected ticks taking place on April 30th. It was thought advisable to take the precaution mentioned, though as this chick also came from an uninfected district, was perfectly well and harboured very few ecto-parasites, it was perhaps scarcely necessary. Still, it is well to avoid every possible source of fallacy. On June 2nd the chick was found infected, the incubation period being very brief, but it must be remembered that spirochætes can be much more readily detected by the dark-field than by any other method, and hence old views on incubation periods in spirochætosis may require revision. At the same time, it is worthy of note that by June 3rd the infection was heavy, and the bird died on the evening of June 4th.

I think these two experiments prove conclusively that spirochætal infection in fowls can take place per os. The other two experiments—one negative, the other positive—were carried out with ticks which, so far as could be told, only harboured spirochæte granules. I say "so far as could be told," for it is not possible, of course, to dissect and examine fully every tick of the batch used for feeding the chick. As Leishman[8] says: "This fallacy is one which is always present in such work as that under consideration. For example, whatever conclusion one arrives at as to the condition of a given batch or brood of ticks must be founded on the examination of a sample of such batch. However large the sample, and there are obvious limits to this where it is desired to follow up the course of subsequent events in such a batch, any conclusion is open to the objection that a different condition existed in a member of the group which was allowed to survive. Conservative surgery in the case of a tick is unfortunately impossible." I have, however, found that a mild form of conservative surgery is possible in ticks. One can snick the edge of the body and obtain a drop of mixed cœlomic and intestinal sac fluid, sufficient for dark field examination without doing the tick a fatal injury, and this technique has proved very useful in some of the work. It was employed in the following experiments, and in addition ticks were dissected and certain of their tissue, especially the Malpighian tubes, examined both by the dark-field and as stained preparations. In no case were any spirochætes found.

[8] Loc. cit.

Experiment 3.—A chick was given nine ticks which 12 days previously had fed on a bird with spirochætosis and which, as noted, only showed granules. The chick ate them all, but never developed spirochætosis. That it was not immune was shown by the fact that at a later date it was successfully inoculated in the usual way with spirochætal blood.

Experiment 4.—June 15th, 1911: A healthy chick, free of all vermin, was given, and devoured at once, 14 starved ticks which had last fed on March 20th, 1911, and then on a bird with acute spirochætosis. As noted, these ticks only contained granules. The granule infection was heavy. No developmental forms were seen. Since feeding the ticks had been kept at laboratory temperature. On June 17th the chick, which had been protected in the usual way, developed spirochætosis, and the disease ran a severe course, terminating in death.

Do the granules penetrate the mucous membrane as granules or as young spirochætes? The first is most likely, full development probably taking place in the blood or organs of the chick. This, however, is not a question easily settled, but the result of the experiment is very interesting. It will be necessary to carry out confirmatory work, but there seems little doubt that the infective granule is as infective when administered per os as it is when injected subcutaneously.

Khartoum.

A FATAL CASE OF PHLEGMONOUS INFLAMMATION OF THE DUODENUM FOLLOWING IMPACTION OF A FISH BONE.

BY GORDON TAYLOR, M.A. ABERD., M.S., B.SC. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL;
AND
C. ERNEST LAKIN, M.D. LOND., M.R.C.P. LOND.,
ATHOLOGIST TO THE MIDDLESEX HOSPITAL; ASSISTANT PHYSICIAN TO THE BOLINGBROKE HOSPITAL.

ACUTE phlegmonous inflammation of the gastro-intestinal tract is a condition met with very infrequently. Cases of acute phlegmonous gastritis, however, are recorded from time to time, and the subject is thoroughly dealt with in the monographs dealing with diseases of the stomach. The intestine, to judge from the cases recorded, is much less frequently the site of this particular lesion; thus, MacCallum [1] [2] in 1906 could only collect seven cases from the literature, of which five affected the small intestine exclusively. The following case, therefore, would seem worthy of publication.

A woman, aged 66 years, was admitted into the wards of the Middlesex Hospital on the evening of Feb. 9th, 1911, with a diagnosis of acute appendicitis. She had suffered from "bilious attacks" for some years. Thirty-six hours before admission she had been seized with a pain in the abdomen and had vomited repeatedly. The bowel had acted once as a result of an enema. Her pulse was 124, small and feeble, and her temperature was 101° F.; her respirations were not appreciably quickened. The abdomen moved fairly well on respiration, and the tenderness was found to be most marked in the upper part on the right side and towards the middle line at a distinctly higher level than is usually met with in cases of appendicitis, and an indefinite swelling could be felt in that region. This was particularly noticeable afterwards when the patient was anæsthetised. The diagnosis of appendicitis was put aside and that of acute pancreatitis suggested. Immediate operation was decided upon. Under anæsthesia the abdomen was opened through the right rectus and a swelling was at once met with in the region of the head of the pancreas and the duodenal loop. No free fluid was present in the peritoneal cavity and there was no evidence of diffuse peritonitis. The appendix was examined and found healthy. Attention was once more directed to the pancreas, the head of which was swollen and firm, and although no areas of fat necrosis were visible on the omentum or in the mesentery, this was not regarded as negativing the diagnosis of an acute inflammation of the pancreas. On more thoroughly exposing the organ it was found to lack the somewhat characteristic plum colour usually associated with an acute infection, but several incisions were made into it and a large drainage-tube was passed down and brought out through the abdominal wound. The curious infiltration of the duodenal wall was remarked upon at the time of the operation, but it was regarded as being secondary to the changes in the pancreas, although later events proved that the very reverse was the case. The abdominal wall was closed by through-and-through sutures of silk-worm gut. The patient returned to the ward, and was treated in the ordinary way by rectal salines and the Fowler position. Her temperature the next morning was down to 98°, but subsequently it rose to 101°, and the pulse became rapid, the abdomen more distended, and the vomiting persisted. She died some 36 hours after the operation. The urine contained albumin, but no sugar. No examination for Cammidge's crystals was made.

Post-mortem examination.—Signs of acute peritonitis were found on opening the abdomen, the various coils of intestine being adherent through the medium of a purulent exudate. The second part of the duodenum showed considerable thickening, and its peritoneal coat presented small patches of fibrinous exudate. On laying open this portion of the gut the mucous membrane was found to be separated from the underlying coats by a collection of pus, which was infiltrating the submucous layer. In places the mucous membrane was raised into projections by the submucous infiltration, and one of these elevations was of the size of a large hazel nut. The ampulla of Vater was patent and the common bile-duct showed no sign of infection. On more careful examination a fish bone was found partially buried beneath the mucous membrane with its free end projecting into the lumen of the bowel. It was an inch and a quarter in length and its point was situated in the midst of the infiltrated area about half an inch below the caruncula major. Infection had spread to the outer coat of the bowel and diffuse peritonitis had thus resulted. The stomach and the rest of the intestinal canal were natural, save for the peritonitic changes. Examination of the portal vein and its tributaries revealed no ante-mortem clotting. The head of the pancreas was slightly swollen, but the rest of the organ was normal, and there was no sign of hæmorrhage or fat necrosis. There was a fibrinous exudate over the base of the lower lobe of the right lung. The liver was pale and fatty.

Section of duodenum, showing penetration of its mucous membrane by a fish bone. Great thickening of the duodenal wall due to purulent infiltration of the submucous coat will be observed. At one spot the infiltration was so great as to lead to the formation of the nodular elevation shown, which exuded pus on incision.

Microscopic examination.—Sections of the duodenum showed that the submucosa was thickened with a purulent infiltration. The muscle coat stained badly, and was similarly infiltrated in parts. Sections of the head of the pancreas exhibited a similar infiltration and the glandular elements had undergone coagulation necrosis.

[1] Phlegmonous Enteritis, Bulletin of the Johns Hopkins Hospital, August, 1906.
[2] H. D. Rolleston: Diseases of Small Intestine, Allbutt and Rolleston's System of Medicine, vol. iii.

Bacteriological examination.—A pure culture of the bacillus coli was obtained from the wall of the duodenum and from the exudate in the pleura. No organisms grew from the portal vein or pancreas. The infection had evidently made its way through the wall of the duodenum between the time of the operation and the patient's death, for when the laparotomy was performed no sign of diffuse peritonitis was present; possibly the manipulations of the duodenum and pancreas at the operation determined this extension of the infection.

Although in our operative and post-mortem experience œdema and infiltration of the duodenal wall have not been met with in cases of acute pancreatitis, yet at the time of operation it seemed quite possible that the latter condition might have interfered with the venous return from the duodenum or that the inflammatory changes in the pancreas had spread by direct extension to the bowel; indeed, Simon and Stanley [3] record two cases of acute hæmorrhagic pancreatitis associated with intense gastro-duodenitis with cellular infiltration of the duodenal submucosa. Post-mortem examination of the present case, however, showed that the pancreatic infiltration was obviously secondary to the acute inflammation of the duodenum.

Fish bones in their passage along the digestive tract may lead to very extraordinary and calamitous results, and they may be arrested at any point from the tonsil to the anal canal. They may produce only slight abrasions in the throat, such as those for which the patient so frequently applies for relief under the impression that the offending body is still impacted, or some disastrous perforation of a large vessel may occur, producing a fatal ending. The presence of a fish bone in an ischio-rectal abscess is not a very rare event, but they have also been known to become impacted in the pharynx and to penetrate the common carotid artery, usually on the left side. They may get impacted in the œsophagus (Rivington,[4] Cripps, Cresswell Rich, Reid) and ulcerate into the aorta (Stephen Mackenzie,[5] Waters); they have produced a left-sided traumatic pneumothorax (Cayley [6]) and an abscess of the lung (Bloxam). They have penetrated the wall of the stomach, the point projecting through the diaphragm into the heart (Andrews [7]). They have been met with in the appendix,[8] and in Wettergren's [9] case of multiple liver abscess with suppurative pylephlebitis, in one of which collections of pus the fish bone was discovered, possibly the latter may have made its way *viâ* the tributaries of the portal vein into the liver from the appendix. Our colleague Dr. A. F. Voelcker has very kindly informed us of a case in which at the necropsy a fish bone was found to have perforated Meckel's diverticulum. The jejunum has been the site of fatal perforation with peritonitis (Coates [10]), and in one case a coil of jejunum was found adherent to the surface of the liver, the latter exhibiting suppurative pylephlebitis; in this case a fish bone was found projecting half an inch into the lumen of the portal vein while the other end was in the jejunum (Winge [11]).

Fish bones appear to have a remarkable predilection for blood-vessels, especially the veins. Apart from the cases mentioned above, where the portal vein was penetrated, cases where the fish bone was present in the superior mesenteric vein had been recorded by Benda, Lambron, and Koch.[12] The impaction of a fish bone in the duodenum appears to be particularly uncommon, and this statement applies to other foreign bodies as well. Somerville Hastings,[13] however, records a case of a pencil impacted just at the bend between the second and third parts of the duodenum which he successfully removed from a girl, aged 3 years, and he quotes several other cases of impaction of foreign bodies in this part of the bowel. One was operated on by Clement Lucas, where a child, aged 22 months, swallowed a French nail 2 inches long; another by Crisp English for a broken bodkin, the sharp broken end of which penetrated the second part of the duodenum. He also mentions Lihotzky's case of a spoon which perforated the duodenum two and a half years after it had been swallowed, when the relations of the viscera became altered by a pregnant uterus; and finally Chaput's case of a tooth-plate impacted in the third part of the duodenum. Possibly the shape of the bend occurring between the descending and transverse parts may determine the site of impaction.

The present case, therefore, has a two-fold interest in that, first, the duodenum is an uncommon site for the penetration of a fish bone; and, secondly, in that the condition produced by the latter—phlegmonous duodenitis—is a very rare condition whatever be its cause. In MacCallum's collected series of cases of phlegmonous enteritis many showed absolutely no sign of any breach of the mucous membrane, whereby the organism could have gained access, but inasmuch as certain of the cases have followed traumatism he suggests that the injury may have produced a point of lowered resistance into which organisms are carried by the blood stream, and he comments upon the relative freedom from bacteria of the uppermost part of the alimentary tube. In most of the cases of phlegmonous enteritis recorded streptococci have been obtained, and in one case in addition a staphylococcus albus was also found. In the present case the colon bacillus was the organism isolated in pure culture, and this suggests that the infection came from within the bowel; and the fact that the patient had had so-called "bilious attacks" before suggests that her duodenum was not sterile. The presence of the fish bone *in situ*, however, seems to prove conclusively that in this case the infection came from inside the duodenum and was not blood-borne.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.—The Portals of Infection in Tuberculosis.

A PROVINCIAL meeting of this section was held at Cambridge on July 8th, Dr. E. CAUTLEY, the President, being in the chair.

Among the cases and exhibits shown were the following:—

Dr. E. J. CROSS: Cretinism in a boy aged 6 years.

Dr. J. A. WRIGHT: (1) Cretinism in a boy aged 15 years. (2) Congenital Heart Disease and Cerebral Hemiplegia in a boy, aged 7 years, who since infancy had been subject to fits. When 18 months old the left leg was noticed to be weak, and it was now smaller than the right. Both knee-jerks were exaggerated. At the base of the heart was a loud systolic murmur suggestive of pulmonary stenosis. (3) Cerebellar Ataxia in a girl, aged 14 years, whose mental condition and power of speech were impaired. She walked with a reeling gait and the knee-jerks were absent. There was also some incoördination of the hands. The symptoms began somewhat suddenly when the patient was 4½ years old. (4) Functional Ataxia in a girl aged 5 years. (5) Heart showing Congenital Malformations. (6) Bones from a case of Infantile Scurvy.

Mr. W. H. BOWEN: (1) Congenital Nævoid Condition of the Left Thigh in a boy aged 12 years (the leg was larger than the right, but gave rise to no discomfort); (2) Chart of a case of Glandular Fever; and (3) Parenchymatous Goitre in a girl aged 16 years.

Dr. L. HUMPHRY: Post-diphtheritic Paralysis in a boy with Unusual Signs.

Dr. E. LL. JONES: Congenital Heart Disease: ? Patent Ductus Arteriosus.

Dr. G. S. HAYNES: (1) Congenital Heart Disease: Pulmonary Stenosis; (2) Tuberculous Disease of the Spine; (3) Mutism; (4) Microcephalic Idiocy; (5) Infantile Paralysis; and (6) Skull of a Mongolian Idiot.

Dr. A. H. MILLER: Chronic Encephalitis (?) in a child aged 7 years.

Dr. J. C. W. GRAHAM: (1) Hydrocephalus and Buphthalmos in a boy aged 3 years; (2) Congenital Cataract in a girl aged 9 years; and (3) Hypermetropic Astigmatism with Macular Changes in a girl aged 8 years.

Dr. C. A. BASKER: Family Cord Disease (spino-cerebellar type) in a boy.

Dr. C. SEARLE: Infantile Spastic Paraplegia in a boy, aged 2 years and 7 months. There was a history of the father having had when a child a sudden attack of paralysis of the right arm, left leg, and right side of the face, with difficulty in swallowing and phonation, which cleared up in 15 months except in the face. One brother had progressive upper neuron degeneration, the effect of (?) an injury, and died totally paralysed, aged 2½ years. The patient, who could not talk, presented a typical spastic paraplegia. The symptoms came on suddenly with a fit when he was 8 months old, and since then he had had frequent attacks of rgidiity with difficulty in swallowing and a high temperature.

Dr. H. B. RODERICK: A series of 27 Pathological Specimens illustrating various bone lesions, symmetrical gangrene of the feet, tuberculous epididymitis, hypertrophic stenosis of the pylorus, sarcomata of the intestines and kidneys, foreign bodies in the glottis, sloughing tonsil involving the internal carotid, and ulceration of the internal jugular vein.

Dr. T. R. C. WHIPHAM: Heart with an infective clot blocking the pulmonary orifice which gave rise to a continuous murmur and was diagnosed as patent ductus arteriosus.

Dr. L. COBBETT: A series of Pathological Specimens from Man and Animals to illustrate his paper on the Portals of Infection in Tuberculosis.

The cases were discussed by the PRESIDENT, Dr. G. PERNET, Dr. T. H. KELLOCK, Dr. L. GUTHRIE, and Dr. H. D. ROLLESTON.

Dr. COBBETT read a paper on the Portals of Infection in Tuberculosis. After giving a historical survey of the subject Dr. Cobbett proceeded to criticise some of the experiments of certain investigators who tried to show that infection took place through the alimentary tract. The forcible feeding of an animal was not easy and often resulted in regurgitation of food, which allowed the infection to be inhaled. The speaker's conclusions, based upon numerous experiments, were to the effect that infection occurred chiefly by inhalation.—A lengthy discussion ensued, in which the PRESIDENT, Mr. C. LUCAS, Mr. R. H. A. WHITELOCKE, Dr. ROLLESTON, Dr. WHIPHAM, and Dr. M. FLETCHER took part.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on July 13th, Dr. Phineas S. Abraham, the President, being in the chair.—Dr. David Walsh showed a case of Cicatricial Alopecia in a girl, in which a diphtheroid bacillus had been isolated from the lesions.—Dr. W. Knowsley Sibley showed: 1. A case of Lupus Erythematosus in a young man which had commenced at the age of 12. 2. A little girl with Alopecia following impetigo capitis, in which the lesion was primarily that of kerion. 3. A man, aged 30, with a Sycosiform Syphilide. The lesions were grouped upon the face and neck and had been present for six weeks. The condition was said to have appeared after a shave.—Dr. W. Griffith showed: 1. A case of Urticaria Pigmentosa of the macular type in a boy aged 4½. The lesions were universally distributed over the body and had appeared at the age of three weeks. 3. A young Russian with Cicatricial Alopecia, probably the result of an old favus.—Dr. J. D. P. McLatchie showed: 1. A case of Acne Necrotica in a man aged 42 2. A little child, aged 1½, with Tubercular Nodules upon the Buttock and Thigh.—Dr. Tom Robinson showed a case of severe Alopecia Areata in a man aged 44. A discussion ensued relative to the etiology of this affection.—Dr. G. Norman Meachen showed: 1. A case of Acne Varioliformis in a man, aged 36, who had suffered from grouped comedones of the scalp when a child. 2. A young married woman with Ulerythema of the Face following slight traumatism. 3. A widow, aged 49, with a peculiar form of Eczematous Dermatitis affecting the face and extensor surfaces of the hands and forearms that had been aggravated by exposure to sunlight.

FIRST PROFESSOR OF EUGENICS.—Professor Karl Pearson has been appointed to the chair of Eugenics, which has been established at the University of London under the legacy bequeathed for that purpose by the late Sir Francis Galton.

Reviews and Notices of Books.

Unsoundness of Mind. By T. S. CLOUSTON, M.D. Edin. London: Methuen and Co. 1911. Pp. 360. Price 7*s.* 6*d.* net.

IN this work the author's intention has been to lay before the "intelligent layman" a presentation of the state of psychiatry as it now is and of the problems with which it is confronted. Dr. Clouston feels that, though the subject does not readily lend itself to popular treatment, the ignorance of mental disorders and defects is such that the need for general enlightenment is very great. The title "Unsoundness of Mind" is used to cover all known mental disorders of whatever sort and from whatever cause, and the author hopes that the intelligent public may be led to take a larger and more humane view of mental disease, that rational efforts at prevention may be made, and that early symptoms may be sooner recognised and therefore the sooner treated. We sincerely hope that Dr. Clouston may find his laudable hopes at least in part fulfilled, and we find it difficult to suppose that it would be possible to present the case with greater simplicity and perspicacity. We hope also that the book will reach the right persons among the "intelligent public." Our own painful experience is that works written for the general public fall, for the most part, into the hands of persons who, though intelligent, are unbalanced; and who use such information as they may glean, often curiously distorted, for the purpose of bolstering up some freak social theory, or to find a tag wherewith to label their own supposititious symptoms, or upon which to found a system of inappropriate treatment. Over and over again practitioners discover whole trains of symptoms based upon the perusal of some work that was intended to make plain to the populace the obscurer paths of medicine; and, indeed, in some cases have been able to tell the patient what he has been reading. There must, for instance, be few of the profession who have not suffered from the popularisation of the "uric acid diathesis," though from it we are at least having a rest during the exploitation of the lactic acid bacillus. If, however, the self-diagnosis and self-treatment of mental disorder of the less-important and less-marked forms are to become at all prevalent, we must brace ourselves for no common ordeals.

The author is very emphatic on the subject of heredity in mental disease, and agrees with Dr. C. A. Mercier and the majority of psychiatrists that it is upon inheritance that depends the stability or instability of the individual's highest nervous arrangements. If this indeed be so, there is little doubt but that the truth should be preached as emphatically in the consulting-room as it is in public, and that it is the duty of the physician to be less weak-kneed than he often allows himself to be. No advice is more likely to be disregarded than advice not to marry, where love or interest urges marriage, but at any rate the good seed is sown when the physician declines to say that there is no danger, or but little danger, when two neurotic stocks come together. It is curious to note how divergent are the views of neurologists and psychiatrists upon the subject of mental disease. We observe that Dr. Clouston tends to throw cold water upon mental worry or stress being the cause of mental disorder, and regards the worry as often being but an initial symptom of the disorder. On the other hand, among neurologists who have to do with the psycho-neuroses the mental causation of those affections appears to be more and more laid stress upon. Whether it is that the psychoses have an essentially different causation to the psycho-neuroses to which they have such an extraordinary

clinical resemblance, differing really in degree rather than in other characteristics, or whether it is that the divorce in practice of neurology from psychiatry colours the views of observers, it is most difficult to determine; but it is probably at least agreed that in the early stages, when symptoms are mild and when it is difficult to determine whether a patient is displaying a psychosis or is merely suffering from a psychoneurosis, it is desirable that disturbing mental factors should be sought for and, if possible, removed. The author enunciates the wisest of advice with respect to preliminary and early symptoms of mental disorder, and it would be indeed of service if this part of the work, at any rate, could be placed in the hands of potential sufferers. Another chapter, that on the training of character, is admirable, and for ourselves we feel that, however the controversy between those who urge mental factors as against those who urge somatic factors as being the most prominent in the etiology of mental disorder may eventuate, a basis of good education and the evolution in the individual of character in the best sense of the word constitute the most perfect prophylaxis at present known.

Contribution à l'Étude de la Physiologie Normale et Pathologique du Péritoine, ainsi qu'à l'Étude du Traitement Rationnel de son Inflammation Aiguë ou Chronique. Par le Dr. MARC ROUSSIEL. Annales de la Société Royale des Sciences Médicales et Naturelles de Bruxelles. Tome XIX., Fasc. 2, 3, et 4. Bruxelles: Henri Lamertin. 1910. Pp. 490.

THE peritoneum is an intensely interesting membrane, though few will have time to read about 500 pages to get at the facts and opinions of the author. But this memoir represents work carried out over four years. It is divided into seven chapters, Chapters I. to V. being devoted to the physiological and pathological aspects of the question and the last two to its purely clinical and practical aspects; and all lead up to the author's method of treating inflammations of the peritoneum from any cause by means of a current of oxygen perfused or percolated through the abdominal cavity after laparotomy has been performed for any reason. The author in the last chapter gives a series of cases of acute general and localised peritonitis treated by this method, with careful details to be observed before the operation, the means of preventing shock, the operative procedure, the introduction of oxygen, and the post-operative procedures, especially as regards the position of the patient. The cases include such as the following: general peritonitis resulting from rupture of the gall-bladder, inguinal hernia, ovarian cysts, and pyosalpinx. The author claims that the introduction of oxygen into the abdominal cavity increases the number of leucocytes in the exudation into the peritoneum, and retards the absorption of fluids introduced into that cavity as well as the absorption of septic effusions. It also stimulates the phagocytic properties of the leucocytes towards bacteria, increases general leucocytosis, helps the heart's contractions, and favours peristalsis and the regeneration of the endothelial cells.

The part played by the omentum in such physiological processes is probably large. The omentum is very varied in its appearance in different animals in the embryonic and adult stages of life. In some animals it is nearly a complete membrane, while in others it is fenestrated and prone to become a point of election for the deposition of fat as well as the seat of very characteristic pathological changes. When carmine or soot or other inert particles are introduced into the abdominal cavity they do not remain disseminated generally in the cavity. On the contrary, in a few hours most of them will be found in the omentum, so that if carmine be used it is red, if soot it is black; hence it has been called the "sweeper up," or "balayeur," and hanging as it does it is admirably placed for this purpose. It also absorbs microbes, some of which remain in the membrane, and some are carried and deposited in the retro-sternal lymphatic glands and near the pylorus, but they do not appear to go direct to the liver, as was suggested by F. Heger. It is, therefore, a great protective organ against the invasion of micro-organisms. As absorption is most active in relation to the diaphragm and the omentum, an injected patient should be so placed that the fluids will gravitate downwards. Dr. Roussiel gives elaborate blood counts of the effects of the introduction of oxygen, air, carbon dioxide, or nitrogen into the abdominal cavity. He also describes the effects produced by artificial inflammation, set up by injecting aleurone grains into this cavity in animals. There are several excellent colour plates of leucocytosis.

This is a distinctly interesting contribution to the physiology, pathology, and therapeutics of the peritoneum and the omentum. It should be read by abdominal surgeons as well as by gynæcologists.

Alcoholic Fermentation. By ARTHUR HARDEN, Ph.D., D.Sc., F.R.S., Head of the Biochemical Department, Lister Institute, Chelsea. London: Longmans, Green, and Co. 1911. Pp. 128. Price 4*s.* net.

IT would be hard to find any scientific worker better qualified to deal with the vast subject of alcoholic fermentation than the author of this volume, the chapters in which are based on an admirable series of lectures delivered by him at the London University and the Royal Institution during 1909 and 1910. His own stimulus to some very fruitful work in this direction came from Buchner's great discovery, the preparation from yeast of a liquid which, in the complete absence of yeast cells, was capable of resolving sugar into carbon dioxide and alcohol. This discovery of zymase, which name Buchner decided to give to the active liquid, introduced, as the author points out, a new experimental method by means of which the problem of alcoholic fermentation can be attacked; and the result has been that since 1897, when the discovery was made, a considerable amount of information has been gained with regard to the nature and conditions of action of the enzymes of the yeast cell. It was soon found that fermentation was not the simple matter that might have been expected from such a simple way of separating its initiator. To begin with, zymase, though essential for fermentation, cannot of itself bring about the alcoholic fermentation of sugar, but is dependent, as Dr. Harden explains, on the presence of a second substance termed, for want of a more reasonable name, the co-enzyme. "The chemical nature and function of this mysterious coadjutor are still unknown, but as it withstands the temperature of boiling water and is dialysable it is probably more simple in constitution than the enzyme. This, however, is not all; for the decomposition of sugar a phosphate is also indispensable. It appears that in yeast juice, and therefore also most probably in the yeast cell, the phosphorus present takes an active part in fermentation and goes through a remarkable cycle of changes. The breakdown of sugar into alcohol and carbon dioxide is accompanied by the formation of a complex hexosephosphate, and the phosphate is split off from this compound and thus again rendered available for action by means of a special enzyme termed hexosephosphatase. In addition to this complex of ferments, the cell also possesses special enzymes, and the co-enzyme can be destroyed, and further, at least one substance, known as an anti-enzyme, which directly checks this destructive action." Such, in the author's words, may be taken to be the summary of the present position—a position which has been reached largely by his well-known contributions to the

subject which have been published in the *Journal of the Chemical Society* and other scientific publications.

The book is a most interesting and instructive review of the attempts, ancient and modern, which have been made to unfold the secrets of the great alcoholic fermentation processes.

Précis d'Obstétrique Opératoire. By Professor DE SEIGNEUX, Professor in the Faculty of Medicine in the University of Geneva. Deuxième Partie. Geneva: Librairie Kündig. 1911. Price 5 fr. alone; three volumes, 15 fr.; or in one volume, 17 fr.

IN the third volume of his work, the first two volumes of which were reviewed in THE LANCET of May 13th, Professor de Seigneux considers the methods of extracting breech presentations, version, embryotomy, posterior parietal presentations, prolapse of the cord, brow and face presentations, placenta prævia, rupture of the uterus, contracted pelves, and asphyxia neonatorum. This volume has all the merits of the first two, and the illustrations are particularly good and very numerous. We may call attention particularly to the series illustrating the operation of version. We are surprised, however, to note that the author apparently does not describe external cephalic version in breech presentations—a mode of treatment of great value in such cases. In describing the operation of decapitation he rightly calls attention to the deficiencies of Braun's blunt hook, but recommends in its place the complicated and equally unsatisfactory embryotomes of Ribemont, Dessaignes, and Bond. In the chapter on rupture of the uterus no attempt is made to discuss the treatment, but the practitioner is recommended to transfer the patient as speedily as possible to the nearest hospital—no doubt excellent advice, but which it might be impossible to carry out in many circumstances and for obvious reasons. In a case in which the practitioner is compelled to act on his own responsibility he would obtain no assistance from consulting this book, and this seems to us to be a serious omission.

The statement of the author that the induction of premature labour is attended with a maternal mortality of 1–1·4 per cent. and a fœtal mortality of 37·3 per cent. hardly represents the entire truth. It must be borne in mind that many of the deaths in the cases collected by von Sarwey, from which these figures are quoted, included such conditions as eclampsia, acute anæmia, kidney disease, rupture of the uterus, heart disease, and phthisis, and in reality all these deaths ought to be deducted in an attempt to arrive at the true mortality of the induction of premature labour. The point is, however, a small one, but it serves to show the caution with which figures should be regarded. With the principle which the author is supporting in this chapter all will agree—namely, that "the medical man who engages to attend a patient in her confinement is morally bound to preserve her from danger by all the means which the obstetrical art places at his disposal."

The second part of this book should prove as useful as the first and the whole work is a good example of its kind.

Hautkrankheiten Sexuellen Ursprungs bei Frauen (Skin Diseases of Sexual Origin in Women). By Dr. OSKAR SCHEUER. Berlin and Vienna: Urban and Schwarzenberg. 1911. Pp. 204. Price, paper, M.8; bound, M.10.

WHILE it is an undoubted fact, as Dr. Oskar Scheuer points out in his preface to this book, that large numbers of skin diseases owe their origin to purely local conditions, yet there are many others dependent upon pathological changes in certain of the internal organs. The advances that have been made of late years in our knowledge of the action of the various internal secretions have enlarged our conception of many of the problems concerned with the causation of certain skin diseases. The close relationship between dermatology and general medicine is, of course, well known, and the best skin specialist is he who has first studied and practised general medicine.

In this book the author attempts to show the relationship between certain conditions of the sexual organs in the female and certain skin diseases. That such a relationship exists he is certain, and every gynæcologist could quote cases in which such a condition appeared to exist. Of necessity hypothesis must play a large part in any attempt to explain the connexion between affections of the genital organs and skin diseases. In spite, or because, much here is still very problematical, the subject is one of great interest. The author discusses seriatim, after a preliminary consideration of some historical points and general principles, the relation of puberty, chlorosis, menstruation, disease of the sexual organs, and pregnancy to, and their possible effect upon, certain skin diseases. Chapters are also devoted to a consideration of the possible connexion of labour, the puerperium, and the climacteric with the same skin affections. When we consider the profound changes, both in the body as a whole and more particularly in the nervous system, that are associated with such epochs of a woman's life as puberty and the menopause, it is not surprising to find that the skin may undergo changes in common with many other parts of the body. The development of the body hair at puberty, the pigmentary changes in association with pregnancy, the flushing of the vessels of the skin with blood so frequently an accompaniment of the menopause, all tend to show the intimate connexion between the genital organs and the skin at these periods of life. As Dr. Scheuer maintains, in many cases the development of certain dermatoses is to be explained, not by any direct action of the internal secretions upon the skin, but by an increased vulnerability of that portion of the body produced by the action of these secretions.

The whole question is one of considerable interest, and both to the dermatologist and to the gynæcologist this book will prove interesting and instructive.

Chaleur Animale et Bioénergétique. Par JULES LEFÈVRE, Agrégé de l'Université, Lauréat de l'Institut et de la Société de Biologie. Préface de M. A. DASTRE. Avec 211 figures dans le texte. Paris: Masson et Cie. 1911. Pp. 1107. Price 25 francs.

THOSE readers who are conversant with the *Journal de Physiologie* in its later years know full well the many excellent memoirs which the author of this *opus magnum* has published on the subject of animal heat, a subject often but imperfectly dealt with in courses both of physiology and of pathology. We cannot wonder, therefore, when we have before us what undoubtedly is one of the best, most comprehensive and original books on this subject in any language, if we find the erudite professor of physiology in the Sorbonne in Paris, Professor Dastre, not only giving it his blessing but saluting its advent as a work than which no better has appeared in biological literature during the last 20 years. It should be in the hands of every physiologist and pathologist as well as in those of the physicist, and be a *vade-mecum* for all three. The hygienist, as well as the medical man, will find much to enlighten and interest him therein. It is impossible to give an adequate idea of the complexity and far-reaching relations of this subject, but perhaps it may help if we give the barest outline of its chief contents.

In an introduction of a few pages the author deals with the ideas held on this subject before Lavoisier, with the work of Lavoisier, of Dulong and of Despretz, of Regnault and Reiset, and with the material balance or metabolism

according to Boussingault, and gives a criticism of them all. The work itself is divided into four books. In Book I. Physiological Calorimetry, Direct and Indirect, is dealt with. The whole thermo-chemistry of foods is considered in all its relations, respiratory exchanges, and the application of calorimeter and other methods for the determination of the gain, loss, and transformation of bodily energy, the work of Atwater being given very fully (pp. 21–228). Book II. treats of Thermo-regulation, or Thermotaxis and Thermogenesis, with an introductory chapter on heat as an excitant in relation to living beings and its action on living beings, and then on the human organism as a whole. Next, the topography of temperature, homoio-thermal and poikilo-thermal animals, oscillations of temperature, normal and pathological, and the means of regulating the temperature by mechanisms more or less complete and varied are considered (pp. 229–610). Book III. deals with what the author calls "Études de Bioénergétique"—i.e., energy in all its relations to living matter. There are many chapters on thermo-chemistry, thermo-dynamics, and muscular activities and fatigue (pp. 611–804). In Book IV. the subject is continued and considered in its application to general physiology, dealing especially with the energy value of foods, the extent to which they are utilised in the intestine, the equivalent energy value of different kinds of food, and the whole question of dietaries and the "reserves" of the body (pp. 805–1037). There is a full and ample index.

We have said enough to show the magnitude and high scientific character of this treatise, which carries forward in such a comprehensive, exact, and characteristic manner the last traditions and knowledge of a subject whose exact foundations were laid by Lavoisier, so much so, indeed, that this subject has been claimed as essentially a French science. We give the work a warm and hearty welcome.

LIBRARY TABLE.

Handbook of Medical Treatment, a Guide to Therapeutics for Students and Practitioners, with an Appendix on Diet. By JAMES BURNET, M.A., M.D. Edin., M.R.C.P. Edin., Lecturer on Practical Materia Medica and Pharmacy; Physician to the Marshall Street Provident Dispensary, Edinburgh. Edinburgh: John Currie. 1911. Pp. 168. Price 3*s.* 6*d.*—The author of this work in his preface states that the present manual "is an unambitious attempt to supply the main facts of medical treatment within the compass of a small volume convenient to handle and to carry about." The diseases are placed in alphabetical order, and the directions for treatment are given very briefly. So far as these directions go, they are accurate and well expressed, but they are too brief to be of any true value. The success of treatment lies in studying each patient individually, and not in giving the same drugs in every case of any particular disease. In the volume now before us this principle is not sufficiently emphasised, and if the directions therein given are always followed, mere empiricism and not rational therapeutics would be the result. For rapid reference as to hints for treatment this book may be useful, but as a "handbook" of medical treatment we cannot comment favourably on it.

Deutsche Heil- und Pflegeanstalten für Psychischkranke in Wort und Bild. Redigiert von Dr. JOHANNES BRESLER. Halle a.S.: Carl Marhold Verlagsbuchhandlung. 1910. Pp. 666. Price M.28.—This work constitutes a guide book on a very large scale to the various institutions for the mentally disordered in the German Empire. It is well and profusely illustrated and contains many ground-plans of the various buildings described, so that a reader gets a very good idea of the character of the institutions. Perhaps the most striking feature is the development of the villa system, so that many of the hospitals resemble garden cities and are considerably less barrack- or prison-like than are similar places in our own country. In many institutions patients are divided into classes according to the disease with which they are afflicted, and it is satisfactory to note that the treatment of acute mania by rest in bed is widely practised. The book would be very useful to anyone whose duty it became to take part in the building of a new asylum.

The Essentials of Materia Medica and Therapeutics for Nurses. By JOHN FOOTE, M.D., Assistant Professor of Therapeutics and Materia Medica, Georgetown University School of Medicine, &c. London and Philadelphia: J. B. Lippincott Co. 1910. Pp. 194. Price 4*s.* 6*d.* net.—This book limits the number of important remedies to be studied, briefly noticing other frequently used drugs and preparations in an appendix. The classification according to chemical and botanical groups is avoided as needless for those for whom the book is intended, and the drugs are grouped at once under their therapeutic properties and uses. The book contains six chapters relating to definitions, weights, and dosage; how medicines act, important drugs and medicines, hypodermic and rectal medication, a reference list of commonly used drugs, chemicals, and proprietary medicines, and therapeutic definitions and abbreviations. It seems on the whole to contain a good deal of useful information and not to be overloaded with unnecessary detail. It is, however, in parts loosely written. We should like to know when the plurals of *infusum* and either *emulsum* or *emulsio* became *infusæ* and *emulsæ* (p. 11). On p. 47 we are told that "when a solution of a soluble iron salt, such as the chloride, is added to albumin, it precipitates the latter, forming a compound known as an albuminate. Mercury compounds destroy and corrode albumin; iron, however, simply makes albumin insoluble and has no corrosive action." If this sentence does not imply that mercury salts do not form an albuminate we are at a loss to know what it does mean; yet the author himself, on the next page but one, states: "Mercury salts combine rapidly with albumin, destroying it and forming an albuminate which is quickly absorbed."

The Birds of the British Islands. By CHARLES STONHAM, C.M.G., F.Z.S. With illustrations by LILIAN M. MEDLAND. London: Grant Richards, Limited. Part XVIII. Price 7*s.* 6*d.* net.—Mr. Stonham's admirable work is nearing conclusion. The eighteenth part has now made its appearance and only two more sections remain for publication. The eighteenth contains descriptions and pictures of the kittiwake, the razor-bill, the guillemot, the little auk, and the skuas, whose name is said by some to be an onomatopœic reproduction of its cry, but by Professor Skeat to have reference to the Icelandic name for its grey colour. The skuas are very interesting birds. The qualities of the great skua Megalestris cattarrharctes (Linnæus) are summed up in its happy name, which signifies "great pirate rushing down." For these birds, and for that matter others of their kind, live by raids upon gulls and terns, whom they shadow and swoop down upon, forcing them to disgorge the fish which they have just swallowed. The great skua only breeds in Unst and Foula in the British Islands, though the bird is occasionally driven further inland by tempestuous weather. It is extremely brave both against man and dog when defending its young. Another skua, the pomatorhine skua, which is more abundant in the British Islands and more widely distributed, is called stercorarius, the old idea being that the food which it obtained by chasing gulls and terns was voided from the bowel of the victims and not from the gullet. The whole family are very interesting, appearing to be innate criminals, who prefer to secure sustenance by robbery, although there is no apparent reason why they

should not obtain their food by honest effort. Miss Medland's pictures are very good in this part.

The Student's Handbook of Surgical Operations. By Sir FREDERICK TREVES, Bart., G.C.V.O., C.B., LL.D., F.R.C.S. Eng., Serjeant-Surgeon to H. M. the King, Consulting Surgeon to the London Hospital; and JONATHAN HUTCHINSON, F.R.C.S. Eng., Surgeon to, and Lecturer on Surgery at, the London Hospital. Third edition, revised throughout. With 162 illustrations. London, New York, Toronto, and Melbourne: Cassell and Company, Limited. 1911. Pp. 512. Price 7*s.* 6*d.*—The progress of surgery makes it compulsory that any work on this subject for students should be frequently revised, for old operations drop out of use and new operations appear, and it is essential that only those methods which are current should be described. This useful manual has been subjected to thorough revision by Mr. Jonathan Hutchinson, and it may be taken to represent very closely present practice. For instance, lumbar colotomy and lateral lithotomy are no longer described in this volume, for these operations are never now performed. We are glad to see that severe efforts have been made to keep down the size of the volume, for it is essential that works for students should not be too large. In this book the student will find all the knowledge on operative surgery which he will require for the ordinary examinations. We can commend it with confidence.

On Writing Theses for M.B. and M.D. Degrees. By H. D. ROLLESTON, M.D. Cantab., F.R.C.P. Lond. London: John Bale, Sons, and Danielsson, Limited. 1911. Pp. 27. Price 1*s.* net. —The substance of this little book first appeared, as we learn from the preface, in the pages of the *St. George's Hospital Gazette*. Dr. Rolleston, as senior physician to St. George's Hospital, in which capacity he is constantly being asked for advice as to writing theses, and as one who has himself been through the mill of composing theses for his baccalaureate and doctorate, writes with both authority and knowledge. His advice may be commended, not alone to those who write theses fo an academic distinction, but also to those who write papers for the medical press. Besides the purely practical advice contained in the book, Dr. Rolleston gives some interesting historical facts as to theses and their maintenance. Disputation and maintenance are still carried out in theory, but except occasionally in a Faculty of Medicine there is but little original work displayed in a thesis. A shadowy remnant of disputations still survives at Oxford in the rule that a candidate for the degree of B.D. shall read two theses on some theological subject approved by the Regius professor, a custom which gave rise to Mansel's witty if bitter epigram,

> "The degree of B.D. it's proposed to convey
> To an A double S by a double essay."

But theses have to be written also for degrees in medicine, and Dr. Rolleston's advice will certainly be found most helpful to those who have to write them.

Famous Castles and Palaces of Italy. By EDMUND B. D'AUVERGNE. Illustrated in colour from paintings. London: T. Werner Laurie. 1911. Pp. 320. Price 15*s.* net.—The author of this book has opened up, we believe, new ground, for, often as the cathedrals, the churches, the monasteries, and the art galleries of Italy have been described, the castles have so far escaped any systematic notice. This is possibly because the castles of Italy do not form, as, for example, did the numerous castles of the Anglo-Welsh border, one systematic scheme of offence and defence. The Italian castles are fortuitously situated, they were not necessarily fortresses but often the seats of reigning families, and the historical events with which they are connected have to do with the strife of separate ducal clans and not with the struggles of a king against his people. The detailed history of some of them in consequence is hard to come by, but others, like the castle of Sant' Angelo at Rome, are associated with historic events of real importance. Lurid stories of crime and wrong, and the terrific episodes arising out of the struggle between the mediæval republics of Italy and their rulers, and between their rulers and Emperor or Pope, are largely buried in the archives of extinct States, and Mr. D'Auvergne is to be thanked for the industry with which he has unearthed some of these interesting details, and the skill with which he has woven them into a homogeneous volume. The beautiful illustrations, seven of which are in colour-reproductions from paintings by Mr. C. E. Dawson, give faithfully the appearances of such well-known buildings as the Castle of Sant' Angelo, the Castle of Ferrara—scene of the loves of Parisina and Ugo—and the Bargello at Florence, now the National Museum, and containing a splendid collection illustrative of Italian mediæval art.

Meat and Food Inspectors' Examinations: Model Answers to Questions Set by the Royal Sanitary Institute and Other Examining Bodies. Compiled by G. T. BILLING, Meat Inspector, Metropolitan Borough of Finsbury; and A. H. WALKER, Sanitary Inspector, Metropolitan Borough of St. Pancras. London: Sanitary Publishing Co., Limited. 1911. Pp. 156. Price 3*s.* 6*d.* net.—This book contains a collection of questions actually set at the examinations for meat and food inspectors, which should be of use not only to candidates for that examination, but also for intending candidates for the examinations of the Sanitary Inspectors' Examination Board, the Royal Sanitary Institute, and the Board of Education examination in hygiene. The questions, which are grouped under such headings as slaughtering, cowsheds, signs of disease and health in living animals, general diseases of animals, fowls, and fish, appearances of flesh and fat in various animals, organs in health and disease, carcasses, butchers' joints, parasitic and bacterial diseases, and preservation and storage of food, are supplied with "model" answers. On reading aloud the questions and answers, they give the very practical effect of listening to a *viva voce* examination. Besides flesh food, butter, milk, cheese, eggs, coffee and tea, flour, lime-juice, beer and porter, potatoes, and canned foods are dealt with. There are also questions on the legal powers and limitations of inspectors. The answers are direct, clearly expressed, and to the point, as all examination answers should be, and, so far as we have tested them, they appear to be accurate, affording a very good survey of the subjects dealt with. The regulations for the examination and the syllabus of subjects are prefixed.

JOURNALS.

The Medical Chronicle.—In the June number of this magazine Dr. W. B. Warrington discusses the subject of injury as an etiological factor in the causation of some well-defined nervous diseases, such as tabes dorsalis and disseminated sclerosis, and also tabulates the diagnostic points distinguishing some of these affections. Dr. G. E. Loveday writes on the laboratory diagnosis of syphilis, dealing with Wassermann's reaction and the different modifications introduced into the technique of the test, and also with some other reactions, such as the meiostagmine test, Porges' reaction, and so forth.

Bristol Medico-Chirurgical Journal.—In the June issue Mr. Ernest W. Hey Groves writes on resection of the posterior spinal roots, which he holds to be free from

much danger and to be useful for the control of visceral crises in tabes dorsalis and also a means of relieving spasm in diseases of the pyramidal tracts. We refer our readers to the papers on the subject recently published in THE LANCET. Dr. William Cotton describes, with diagrams, an elementary radiographic camera; Dr. Bertram M. H. Rogers discusses the medical aspect of Boswell's "Life of Johnson" and gives some account of the medical men therein mentioned; and Dr. J. O. Symes contributes some observations on school hygiene. Dr. R. Shingleton Smith gives a personal experience of furunculosis, in which he found Bier's cupping both painful and useless, while the application of strong solution of iodine was most efficacious. Dr. C. E. K. Herapath writes on auricular fibrillation, and gives tracings of some curves obtained with Mackenzie's polygraph; and notes of four cases of cervical cysts probably branchial in origin are given by Mr. Charles A. Morton. Dr. Edward Cecil Williams describes a case of ataxia in a child aged 3½ years.

Edinburgh Medical Journal.—A letter from Dr. Horatio R. Storer giving some reminiscences of the great J. Y. Simpson is published in the July issue of this journal. Dr. George A. Pirie and Dr. Edmund F. T. Price each contribute papers on X ray diagnosis of renal calculi, and Dr. F. Parkes Weber sends a brief note on muscular exercise in relation to heart strain and to neuroses. Mr. J. S. Fraser deals with removal of the faucial tonsils by enucleation, and Mr. Arthur Mitchell considers the operative treatment of varicose veins; while Dr. G. L. Kerr Pringle discusses the classification of some forms of arthritis, especially rheumatoid arthritis and osteo-arthritis.

Dublin Journal of Medical Science.—In the July number Dr. J. B. Story deals with the National Insurance Bill as it affects Ireland. He believes that it will tend to depress wages. A first instalment of Dr. Ernest Hastings Tweedy's annual report of the work at the Rotunda Hospital is also here published. Dr. Douglas Macleod Moffatt writes on medical inspection of schools and the disorders most commonly encountered in such examination; and Dr. J. Singleton Darling and Miss C. Florence Williamson discuss some points in the administration of anæsthetics, speaking favourably of the use of hyoscine and morphine as a prelude to a general anæsthetic and also of the administration of ether by the open method.

The American Journal of Gastro-Enterology. No. 1. June, 1911.—This is the first issue of a new journal devoted to subjects pertaining to digestion, which is published quarterly at 6s. per annum, under the auspices of the American Hospital for Diseases of the Stomach, Philadelphia. The editor is Dr. Lewis Brinton and among his associates and collaborators are several well-known American physicians and surgeons. The contents of this number are—the Surgical Treatment of Gastroptosia, by Dr. H. A. Beyea; Duodenal Ulcer, by Dr. Lewis Brinton; the Importance of the Colloidal Nitrogen in the Urine in the Diagnosis of Cancer, by Dr. M. Einhorn, Dr. M. Kahn, and Dr. J. Rosenbloom; Migraine, with special reference to Disturbance of the Gastric Function an Exciting Cause, with report of 47 cases, by Dr. Robert R. Rhein. Pages 22 to 48 are occupied by abstracts of literature on related subjects. Glancing over the titles of the original articles, all seem subjects that, if adequately treated, deserve a place in a general medical journal; if inadequately, they deserve no place in any journal. We are hardly convinced of the necessity for multiplying special journals in such limited departments of applied medicine.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

(1) EPININE AND COCAINE HYDROCHLORIDE; AND (2) "TABLOID" XAXA AND CAFFEINE.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

(1) Epinine is a remarkable example of the triumph of synthesis; it is the synthetic vaso-constrictor and hæmostatic which acts in the same way as the suprarenal active principle. The advantages of the synthetic preparation are an ensured purity and stability. The combination of epinine and cocaine hydrochloride is obviously useful for local anæsthesia and particularly in dental practice. (2) In tabloid xaxa and caffeine the specific antipyretic and analgesic action of xaxa or acetyl salicylic acid is combined with the stimulating effect of caffeine on the circulation. Its use is therefore indicated in cases of pyrexia in which there is weakness of the heart's action.

X RAY PROOF CLOTH.

(W. S. ROTHBAND AND CO., PREMIER RUBBER WORKS, BENT-STREET, CHEETHAM, MANCHESTER.)

This is a somewhat heavy rubber sheeting which, on analysis, proves to contain metallic lead. The sheet is intended for stopping the action of injurious x rays. On testing the sheet with x rays it proved to be amply effective for all practical purposes. It absorbs, at all events, all rays likely to be prejudicial in x ray operations, and at least 85 per cent. of the total output of an x ray tube of an average degree of vacuum.

LIQUEUR ADVOCAAT.

(WARNINK, AMSTERDAM. LONDON AGENCY, THE VICTORIA WINE COMPANY, 12 TO 20, OSBORN-STREET, LONDON, E.)

This preparation may be regarded as an elegant improvement on the mistura spiritus vini gallici of the British Pharmacopœia, which is an ordinary emulsion of brandy, egg yelk, and sugar to which is added cinnamon water as an aromatic. The advocaat liqueur is the best preparation of its kind we have examined. It is not only a perfect emulsion but a permanent one, its condition remaining unchanged indefinitely, a distinct merit as many emulsions tend to separate. We understand that the egg yelk used is derived under the most favourable circumstances from poultry kept specially for the purpose. Our analysis of advocaat liqueur was as follows: alcohol by volume, 22·82 per cent.; total solid constituents, 45·16 per cent.; and egg fat, in yelk, 7·74 per cent.; coagulable albumin, 5·04 per cent.; mineral matter, 0·19 per cent.; and sugar, 29·05 per cent. The alcoholic strength is about that of port wine. The flavour is bland and attractive. It is obvious that the preparation is a powerful restorative and food.

"TOPMAST" SARDINES.

(ALF. SPRING AND CO., WEST DOCK-STREET, HULL.)

We have already in these columns referred to the peculiar nutritious properties of the sardine, pointing out that, among its advantages as an article of diet, it favours the ingestion of oil. The tinned sardine contains approximately a fourth of its weight of protein and an eighth of its weight of fat. This amount of fat, however, excludes the oil adhering to the fish, which is considerable. It is well known that fats assist in assimilation of proteins, and in particular prevent their cleavage into injurious waste products. We examined samples of the above described brand and found them satisfactory. There was no evidence of corrosion of the tin, neither was any metal found in the oil or fishes. The samples examined included sardines packed

in olive oil, and samples also with tomato. The oil is undoubtedly genuine olive oil, and the preparations possess a good appetising flavour.

ADALIN.

(THE BAYER CO., LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

Adalin is regarded as a mild hypnotic which may be trusted to produce no unpleasant after-effects. It is in a way related to veronal, inasmuch as it is an ethyl acetyl urea, with, however, bromine contained in the molecule. But apparently its therapeutic action is not referable to the bromine, as is the case with ordinary bromides, since this is liberated too slowly, and is therefore only slowly dissociated. Adalin is insoluble in cold water, but soluble in hot, and is practically tasteless and odourless. It is conveniently administered in tablets containing five grains of the drug.

(1) GOLDEN SHRED ORANGE MARMALADE; AND (2) SILVER SHRED LEMON MARMALADE.

(JOHN ROBERTSON AND SONS, PAISLEY AND LONDON.)

Marmalade has become such a popular article of diet, chiefly at the first meal of the day, that the question of its purity and quality is important. It no doubt serves to some extent as a bitter and tonic aromatic, exercising a salutary effect on the gastric centres. These preparations gave excellent results on analysis, showing a total solid constituent of 77·07 per cent., of which 66·66 per cent. consisted of sugar, roughly a half of which was inverted. The orange and lemon occur in fine shreds. The preparations had the appearance of a clear jelly and are attractive to the taste. According to our analysis they are not thickened with gelatin or preserved with chemical antiseptics.

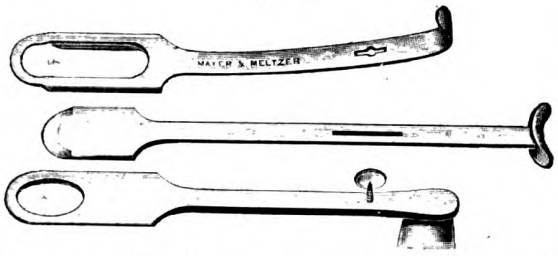
New Inventions.

AN IMPROVED AND SIMPLIFIED ASEPTIC MACKENZIE GUILLOTINE.

IN spite of the many modifications and improvements which have been made from time to time in Mackenzie's guillotine, some of its defects have remained in one or other pattern, and some are common to all: (1) the difficulty of cleaning the groove and slot along which the blade passes; (2) the large number of parts, some of which are small, easily detached, and easily lost; (3) the dependence of the instrument for its proper working upon two screws, the threads of which rapidly wear out, and the fact that these defects usually become manifest during an operation.

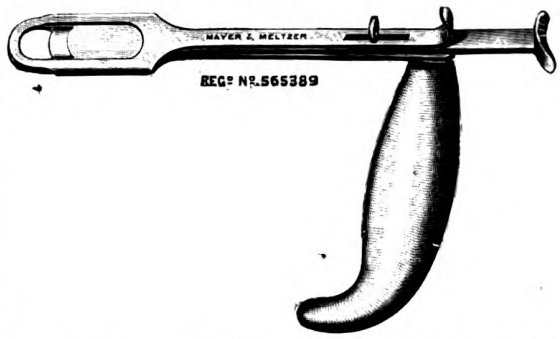
I have devised an instrument in which these defects have been entirely eliminated, and I am indebted to Messrs.

FIG. 1.



Mayer and Meltzer for the great interest they have shown in the instrument and the pains they have taken to produce a really workmanlike tool. The main points of the guillotine may be summarised as follows: 1. It consists of three separate parts instead of, as in most other patterns, six (Fig. 1). 2. There are no screws in it; the handle and turn-button which holds down the spring are permanently attached to the "bed-plate." 3. The "bed-plate" has no grooves at the side or slot at the end, so that it can be cleaned perfectly in a few seconds. 4. The spring and retaining sheath for the blade are in one piece, and as the grooves are open this part also can be cleaned in a few seconds. 5. The handle (Fig. 2) is of an entirely new

FIG. 2.



shape with a slight forward tilt and a forward curve at its extremity, giving great power of lateral pressure against the pillars of the fauces. As this handle, however, has not been found to fit all hands experiments are being made with a view to still further improving it. 6. The instrument can be taken to pieces and put together again in ten seconds, by the watch. 7. A nurse can thoroughly clean and polish the whole instrument, preparatory to sterilising or putting away, in three minutes. 8. An extended trial shows that it is thoroughly efficient in its work, the blade being in perfect apposition to the "bed-plate" and held down by exactly the right amount of pressure applied in the right place.

HUGH E. JONES, L.R.C.P. Lond., M.R.C.S. Eng.,
Honorary Surgeon, Liverpool Eye and Ear Infirmary.
Liverpool.

A SIMPLE NASAL SPECULUM.

FOUR or five years ago I was unexpectedly asked to examine a patient's nose in a country house. I had a frontal mirror, but no nasal speculum. I managed to improvise one with a large hair-pin bent so that the ends of the loops forming the blades overlapped the shanks, thus rendering the blades incompressible. It worked so well that I had a number of these specula in an improved form made by the Holborn Surgical Instrument Company. These instruments have the advantages of being efficient, perfectly sterilisable, and cheap, costing only 6*d.* each. They are thus very suitable for hospital out-patient work or in other circumstances where a ready succession of unused instruments is required.

Laryngologist to the Italian Hospital, London.
Manchester-square, W.

THE BRITISH MEDICAL ASSOCIATION: HONORARY DEGREES.—At the annual meeting of the British Medical Association in Birmingham the University will confer the honorary degree of Doctor of Civil and of Canon Law upon Mr. John Burns, M.P., Sir Francis Lovell (president of the Tropical Medicine Section), Dr. R. H. Chittenden (professor of physiology at Yale), Professor H. Oppenheim (neurologist, of Berlin), Professor Paul Strassman (assistant professor of obstetrics, Berlin), Dr. Byrom Bramwell (President, Royal College of Physicians, Edinburgh); Dr. J. A. Macdonald (chairman of Council, British Medical Association), Dr. R. A. Reeve (ex-President British Medical Association and professor of ophthalmology at Toronto), and Professor G. Sims Woodhead (professor of pathology at Cambridge).

THE LANCET.

LONDON: SATURDAY, JULY 22, 1911.

The National Insurance Bill.

THE progress made in the National Insurance Bill during the past week will be found noted in other columns of this issue, as well as the views and representations of important bodies, as, for example, the General Medical Council, the Royal College of Physicians of London, King Edward VII. Hospital Fund for London, Dublin University (Trinity College), the Royal College of Surgeons of Edinburgh, and the Irish National Party. As far as the medical profession is concerned the situation to-day does not differ much from that of last week. Although the clause of the Bill which defined medical benefits has been closely debated, and the number of proposed amendments has been large, the alterations in the Bill have not been far-reaching, and their essential effect upon the medical profession has not been, as a rule, important. An exception to this statement is the large increase in maternity benefit now offered by Mr. LLOYD GEORGE. Under the new subsection to Clause 8 the wives of workers who themselves work will obtain the double benefit which is quite clearly earned by the double subscription to the insurance fund. The amendment has met with very general approval. The medical profession at large well knows the drain on the resources of the working household that may be caused by the incidence of a confinement, and will commend this more liberal treatment of the mothers of the nation.

Under the heading of medical benefits is of course included sanatorium treatment, and the debate on this subject was an extremely important one. For the first time the House of Commons received from medical men a definite statement as to the part which the properly managed and arranged sanatorium may play in the national health. It was made clear to the House that sanatorium treatment is not a remedy for phthisis, that it is not a panacea for other diseases, that it is not by itself going to eliminate anything in any way whatever, but that the sanatorium in its proper place is a most valuable institution. Dr. CHRISTOPHER ADDISON'S speech setting out the benefits to be expected from the sanatorium treatment of tuberculosis, as well as the terrible cost of this disease to the community, was met with a reply from the Chancellor of the Exchequer that the Government was prepared to recognise that the sanatorium properly used is a most valuable weapon in the campaign against consumption. The excellent memorandum published in THE LANCET last week, and signed by Sir CLIFFORD ALLBUTT, Sir LAUDER BRUNTON, Dr. ARTHUR LATHAM, and Sir WILLIAM OSLER, proves how right the Chancellor and the House of Commons are to take up this view, while the critical remarks made in the course of the debate by, among others, Dr. ESMONDE, Dr. A. P. HILLIER, and Mr. WALTER LONG, are sure to be fruitful. The limitations of sanatorium treatment will be better appreciated by the legislature and by the public now that these have been pointed out, while far more economy will be practised than hitherto in respect of their organisation and maintenance. Mr. LONG made a demand for endowment under the Bill of medical research. It is perhaps not too much to hope, particularly as economy is sure to be practised for the future in the provision and support of sanatoriums, that money will be found to carry on a continuous scientific investigation into the causes which mainly influence the incidence and spread of tuberculosis. These are matters of paramount interest to the public as well as to medical men. The admirable work which has recently been done by the Royal Commission on Tuberculosis is threatened with an immediate end. Before it is too late cannot the very different conclusion be come to by the authorities that it would be wise to keep in working order the valuable research machinery erected by the Commission? The Chancellor of the Exchequer, with reference to the provision for research work under the National Insurance Bill, has recognised the fact that the Bill contains a permission to devote money to scientific purposes, and has pointed out that the Bill contemplates the treatment in sanatoriums not only of tuberculosis, but of such other diseases as may be included by order of the Local Government Board. We hope that Mr. LLOYD GEORGE will give effect to his words by helping to secure the continuation of the excellent scientific work done by the Royal Commission on Tuberculosis.

The memorandum of the Royal College of Surgeons of Edinburgh, which has, we understand, been sent to all Members of Parliament, sets out, with much the same arguments as those which we have previously employed, that delay in legislation is necessary to obtain the views of the medical profession. These, as the College rightly points out, have largely been so far taken for granted. The weighty recommendations of the Royal College of Physicians of London cannot receive consideration without adequate time, but the clause enumerating medical benefits has already been disposed of. While we admit that the Bill has so far received fairly full discussion from the whole House in Committee, the time is all too short for carrying through this intricate piece of legislation. The Chancellor has definitely promised under Clause 14, which deals with the administration of medical benefits, to recommit certain parts of Clause 8 if necessary; when this occurs the unanimity of the medical profession will be put to the test.

The Induction of Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis.

THE principle of keeping an inflamed or injured part at rest is a fundamental one in treatment, and is borne out in many instances by Nature's own indications. The protective function of pain is now generally recognised, since not infrequently pain on movement serves automatically to ensure more or less complete immobilisation of an injured part. The reflex rigidity of the abdominal muscles over

acutely diseased viscera and the separation of inflamed serous surfaces by fluid exudates afford other illustrations of the same general principle. A further light is thrown upon the influence of rest or immobilisation on the course of acute and chronic infective processes by the recent development of the theory of auto-inoculation, to which in its special applications to pulmonary tuberculosis we referred in a leading article in THE LANCET of July 1st. It is now suggested that both active and passive movements, by altering the circulatory conditions about a focus of infection, tend to produce auto-inoculation and thus to lead to general symptoms. It is not surprising, therefore, that the suggestion has been made to immobilise the affected lung in cases of pulmonary tuberculosis. The method introduced by Dr. F. T. ROBERTS of strapping the affected side in cases of pleurisy so as to limit its movement was an early attempt in this direction, and although only of very limited efficacy certainly seemed to lessen the pain and afford some relief to the patient. Dr. M. S. PATERSON has lately shown the importance in febrile cases of pulmonary tuberculosis of keeping the patient absolutely at rest in bed—on much the same plan as in enteric fever—the suggested explanation of the value of this method being that it lessens the auto-inoculations with the products of the bacillary activity. It is obvious that the induction of pneumothorax, leading as it does to collapse and retraction of the lung, can bring about complete immobilisation of the lung. Various attempts have been made to apply this fact practically to the treatment of the disease. Many years ago Dr. WILLIAM CAYLEY endeavoured to treat a case of persistent hæmoptysis by the artificial production of pneumothorax. The attempt failed, and the method was thereafter merely mentioned in the text-books as one of the curiosities of unsuccessful treatment. It has lately been repeated apparently with more success, and the same principle has been applied to the treatment of the disease apart from hæmoptysis. The method appears to have been originally advocated for this latter purpose by FORLANINI in 1882, and was employed by MURPHY in America in 1893. It has also been extensively tried on the Continent. In this country but little attention has been devoted to it until recently. We published in THE LANCET of July 15th an interesting paper by Dr. CLAUDE LILLINGSTON in which the practical details of the procedure are described, together with the indications for its employment, while the risks incurred in consequence are carefully discussed. We also published the clinical accounts of six cases in which artificial pneumothorax had been employed.

The condition of artificial pneumothorax is induced by the introduction through a hollow needle of sterile gaseous nitrogen between the parietal and visceral layers of the pleura. Several methods of effecting this are in use. The original method of FORLANINI, which consists in the introduction of the nitrogen into the pleural cavity through a fine hollow needle, can, according to Dr. LILLINGSTON, be carried out with ease in cases not complicated by pleural adhesions, but he enjoins the most careful attention to every detail of the recently improved technique of its performance. The apparatus required consists of a water manometer, a contrivance for slowly introducing measured quantities of nitrogen, and a hollow needle, these being suitably connected together by tubing fitted with stopcocks in such a way that the lumen of the needle may be connected with the manometer or with the nitrogen reservoir. The character of the needle is a matter of some importance, a large needle being more painful, while a thin-walled one is liable to buckle, or if its lumen is too fine it is useless for the manometric observations which are an essential preliminary to the introduction of the gas. Dr. LILLINGSTON describes the two needles in common use—viz., those of SAUGMAN and KJER-PETERSEN—with their advantages and disadvantages. The spot chosen for the puncture is in one of the axillary lines in the seventh or eighth intercostal space, though the conditions in individual cases have to be taken into consideration, since it is best to choose a spot where the lung is healthiest and to avoid the neighbourhood of cavities or of pleural adhesions for obvious reasons. The needle, connected with the manometer but cut off from the nitrogen reservoir, is introduced under strict antiseptic precautions, a momentary sensation of greater resistance being usually experienced when it meets and punctures the parietal pleura. If the point of the needle is within the pleural space and is not blocked by connective tissue the respiratory variations of the intrapleural negative pressure are shown by the manometer. Typical readings are: −14 cm. of water on inspiration and −6 cm. on expiration. Much slighter variations occur when the needle is outside the pleura, whereas a slight oscillation round a mean pressure about that of the atmosphere suggests that the point of the needle is in the lung. It is essential that the needle should be completely dry, as the presence of fluid within it prevents the intrapleural pressure from being recorded by the manometer. After introduction the needle may be blocked by blood or by connective tissue, and it may, under these circumstances, be necessary to pass a stilette along it to clear it. One of the dangers attaching to the procedure is the possibility of forcing air into a vein. To obviate this SAUGMAN, when in doubt, fits a syringe to the needle and aspirates, assuming that if blood is withdrawn a vein has been punctured. When it is clear from the occurrence of the manometric variations that the point of the needle is within the pleura filtered air or nitrogen is introduced. The quantity at the first injection should not exceed 200–300 c.c., and if there are extensive adhesions the pressure, which should be taken before the needle is withdrawn, may rise rapidly after as small a quantity as 50 c.c. It is recommended to repeat the injections every day, or every other day, until the lung collapses and a positive intrapleural pressure of from 5 to 10 cm. of water has been obtained. For this purpose it may be necessary to give several injections of 500 c.c. each. A pressure greater than 10 cm. appears to produce dyspnœa, sometimes of an alarming character, except in cases strictly limited by adhesions.

The rules for the selection of cases suitable for this treatment can hardly be said to be satisfactorily established. It appears that until recently it was employed only for those with marked fever in which one lung was very extensively diseased and the prognosis appeared almost hopeless, but

good results have apparently been obtained in earlier stages of the disease. Dr. LILLINGSTON, in his interesting discussion of this question, points out that there are certain questions to be settled before the method can be extensively applied to early cases or cases of limited extent—viz., the chances that the compressed lung will expand when the injections cease, and the dangers to life from pleural reflex and gas embolism. He admits that reliable answers to these questions cannot be given until the method has been more widely used. He also mentions as possible dangers empyema, hæmoptysis, tuberculous meningitis, and aspiration of pus into the other lung, and refers to an instance of pyopneumothorax reported by BRAUER and SPENGLER, as a result of adopting another method—viz., direct puncture after exposure of the pleura under local anæsthesia. It seems probable that the two most grave risks—viz., pleural reflex and air-embolism—can be very much diminished by careful attention to details of technique, and it appears that a lung can expand after compression lasting for several years, although it must be impossible to promise the patient a functionally active lung at the end of the treatment. Among the minor complications, serous effusion into the pneumothorax, which occurs in one-third of the cases, severe pain and dyspnœa with the first few injections, tachycardia and surgical emphysema may present themselves. The duration of the treatment appears to be lengthy, extending to as much as two or three years, the pleural cavity requiring to be refilled every month or two. If the inflations are discontinued too soon the disease may flare up when the lung expands. In view of all of these possible risks and complications, we cannot but feel that the method should at present be restricted to severe febrile cases which ordinary methods are failing to influence favourably, and further, that its tentative character should be carefully explained to the patient and his friends. It is obviously not a procedure to be lightly recommended, and until much more information is forthcoming both in regard to its immediate and remote results, it is impossible to form any judgment as to its value. In the meantime the careful record of cases, both successful and unsuccessful, such as those described in our columns by Dr. LEONARD COLEBROOK and by Dr. LILLINGSTON in conjunction with Dr. S. VERE PEARSON and Dr. A. DE W. SNOWDEN, will serve a useful purpose in drawing attention to the method and in encouraging other observers to publish their experience.

Physical Training in Secondary Schools.

EDUCATION is undoubtedly a question of body as much as of mind. The body, like the mind, has to acquire its store of information, to evolve habits of discipline, obedience, coördination, and readiness of response; and these require training as much in the one case as in the other. It is not merely a question of "exercise," as generally understood—that is, of haphazard opportunities for the play of the physical forces of the body. Romping play, field games, sports are useful; but they cannot supply that equable development of all parts of the body or confer that effective self-control which are the result of formal physical exercises in the gymnasium when scientifically devised and intelligently taught and carried out. Each, in fact, is complementary to the other, and each is a necessary constituent of an adequate school life. We welcome, therefore, the Memorandum on Physical Training in Secondary Schools recently published by the Board of Education in which these lessons are very clearly taught.[1] Speaking of the object of physical training, the circular, which is signed by Sir GEORGE NEWMAN for the Medical Department of the Board of Education, says that its physical effect includes the influence on the general structure and nutrition of the body, and he recognises clearly the part played by such training in the prevention or correction of faulty action or attitude of the body or of part of it, and in the development of the neuro-muscular system. The educational effect includes among other results the acquirement of habits of discipline, obedience, ready response, and self-control. The disciplinary effects, however, it is pointed out, must not be over-estimated to the detriment of the recreative effects, any more than in games and amusements their adaptability to the task of human development should be entirely lost sight of in presence of their function of producing enjoyment.

Of the many and various kinds of physical exercises that have been devised and are in vogue the circular considers the Swedish system the most suitable in every way because of the definite form of the exercises, which are capable of control by the teacher as to their effects; because they admit of careful graduation and can be arranged in lessons on a reasoned plan. Other systems—the German, the British, the American—are held to be inferior in the fact that they do not provide a "table" of exercises in which the movements follow one another in a certain recognised order and sequence; they do not maintain a regular and steady progression throughout the training, and they lack a characteristic word of command. The Board therefore recommends that all secondary schools should adopt in principle the Swedish system of physical exercises, the best introduction to which will be found in the Board's official syllabus of physical exercises. The advantages of a gymnasium are considered, and general instructions laid down on such subjects as the length of the lesson, the number of lessons, the place of physical exercises in the time-table, the size of the class, and dress. Regarding the qualifications of the teacher, the Board considers that wherever practicable, an expert trained teacher should be a member of the school staff. As this will rarely be practicable, however, in boys' schools, it is recommended that the member of the school staff who is best qualified for the work should be made responsible for physical training, and to this end he should avail himself of opportunities for improving his qualifications by attending teachers' classes or vacation courses. In girls' schools it is easier to obtain the services of a whole-time fully trained woman, and if there is not sufficient physical work to occupy her time one should be engaged who can take some other part in school work.

The circular finally considers the intimate relation of the

[1] Circular 779. Memorandum on Physical Training in Secondary Schools. 1911. London: Wyman and Sons; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby, Limited. Price 2d.

medical officer of the school to the physical training, and points out the desirability of the arrangements being under his supervision, so that he may, for example, take note of the time allotted to physical exercises, the number and length of lessons, their place in the time-table, and their relation to meals. But the medical officer in this connexion should also study the effect of the training on the development of the pupils, and be particularly on the look-out for fatigue or overstrain. It is easy enough to examine and find out those pupils who are unfit for violent exertion, and to order the special exercises required in certain cases, such as flat-foot, but it may not be so simple to ascertain with certainty the subjects who are in a general way not benefiting by the training. We are fortunately beginning to retreat from the position that seemed some time ago to be becoming prevalent, that the mere filling of the head of the pupil with a mass of information constituted education. The object of education is to develop character mental and bodily and so make worthier men and women. No amount of mere instruction will ever accomplish that, nor will any amount of physical training. The right blend of each is wanted.

Annotations.

"Ne quid nimis."

SMALL-POX IN THE UNITED STATES: A DANGEROUS DOCTRINE.

IN an article on Small-pox in the United States, by Assistant Surgeon-General John W. Trask,[1] of the United States Public Health and Marine Hospital Service, the author gives utterance to the following statement: "That the community is protected by vaccination may be true for certain localities, but that the protection thus afforded is general can hardly be maintained." An assertion so entirely revolutionary, coming from such a source, cannot pass unchallenged, and we look at once for the evidence adduced in support thereof. Having pointed out that "one of the most notable features of the small-pox which has been more or less prevalent in the United States for at least ten years is its extreme mildness and the small number of deaths which it has caused," Surgeon-General Trask tells us that "to explain the small number of deaths in the United States we may presume that either the people are partially immune to the disease or else that the existing infection is extremely mild and non-virulent." Why "either ..... or else"? The two conditions are not mutually excluding. On the contrary, they may be, and probably are, co-existent and reinforcing. A vigorous defensive force does not exclude the possibility of a weak attacking one, or *vice versâ*. With such a total disregard of logic staring us in the face at the onset we proceed with lessened trepidation to the course of the argument. Having settled satisfactorily in his own mind that the mildness of the United States outbreak must be due to either one or the other cause, the author proceeds to investigate the first of his alternatives—a partial immunity to the disease—which in like manner he says "might be the result of general vaccination or a racial characteristic otherwise acquired." Again we ask, why "either ..... or"? Surely in this case, also, neither factor excludes the possible operation of the other. It is at this point in his argument to eliminate the factor of immunity as the cause that he lays down the startling proposition above referred to and proceeds to substantiate it as follows: Japan as a nation is "protected" by vaccination as well as, or even better than, the United States; but in 1907–08 there was in Japan an outbreak of small-pox with 19,101 cases and 6273 deaths. As indicating the relatively small number of unvaccinated individuals, he says that out of 5215 small pox patients 1527 were found who had never been vaccinated. But he also tells us that in this outbreak there were found 242 cases in which the patients had previously had small-pox, and of these 57 died. Now, in an outbreak of such intrinsic virulence that even the major and usually absolute immunity of a previous attack of small-pox fails, the minor immunity of vaccination could surely be allowed a greater margin of ineffectiveness without standing convicted of being a local failure. But we find cited, in order to establish the virulent nature of the attack, the fact that the general death-rate of the disease in 1907 was 42·25 and in 1908 was 32·32, while the death-rate among the unvaccinated was 69·4. To produce a general mean, therefore, of 42·25, not to mention 32·32, the death-rate among the vaccinated must have been proportionately low indeed. Surgeon-General Trask next tells us that "if the non-virulence of the disease in this country [United States] is due to protection by vaccination it would be expected that the mild cases would be found only in those so protected"—another *non sequitur*, dependent upon the illogical hypothesis that if vaccination induces immunity nothing else can do so. If, however, the author means to state, not that "mild cases would be found only in those so protected," but rather that "only mild cases would be found in those so protected," it is pretty safe to assume that, relatively speaking, having regard to the virulence of the epidemic, such will be found to be the case. The author apparently thinks otherwise, for he continues: "That the type of the disease as seen in the United States is due to the protective value of vaccination is shown not to be true for certain localities in which outbreaks of the virulent form of the disease have been reported," and he instances 11 such virulent outbreaks as having taken place in 1910—viz., Bay City, Saginaw, and Lapeer, in Michigan; Cleveland, Ohio; Bee County and Denton County, Texas; Marion County, Oregon; Grady County and Oklahoma County, in Oklahoma; Reno County, Kansas; and New York City. Of these we must leave out of consideration Bay City, Lapeer, Grady County, Oklahoma County, Reno County, Denton County, and New York City, because no reference is made in these reports to vaccination at all. But in all the cases in which reference is made to vaccination the protective influence stands out with remarkable clearness, it seems to us. For instance, we are told that in Saginaw the outbreak was so virulent that from three cases with no deaths in September it jumped to 81 cases with 19 deaths in October and 82 cases with 29 deaths in November. Over 40,000 persons were then vaccinated and three weeks' quarantine was enforced in the city until Nov. 26th, "since which date no case of small-pox has occurred." Of the Cleveland outbreak we are told "there was no instance of the disease in those recently vaccinated." Two mild cases occurred in this virulent outbreak in persons who had been vaccinated respectively 17 years and 45 years previously; two medical students, vaccinated on the day of exposure, had very mild attacks. "All the other cases were among unvaccinated children." In Bee County, Texas, "the health officer of Bee County was called to see a patient who had small-pox. There were nine other people living in the house, all of whom refused to be vaccinated, saying that they preferred small-pox to vaccination. A man and two women from another house who had visited the patient before the nature of the

[1] Small-pox in the United States—Prevalence and Geographic Distribution during the Calendar Year 1910. Compiled by John W. Trask, Assistant Surgeon-General. Public Health Reports, June 23rd, 1911. Washington: Government Printing Office.

disease was known submitted to vaccination. The vaccination was successful, however, only in one of the women. Thus, of the 12 who had been exposed to the disease there was but one who had ever been successfully vaccinated; that is the woman above referred to. This woman did not contract the disease, the other 11 did. The original case and 11 secondary ones made 12 in all, and of these five died. A death-rate of 41·66 per 100 cases." In Marion County, Oregon, 29 cases occurred in a virulent outbreak. Of these, 17 had been vaccinated "at some time or another," but they all recovered, while of the 12 who had never been vaccinated 9 died! Finally, a farmer and his wife, with an unmarried daughter, went to visit their son. In the train they sat near a small-pox convalescent (he was detrained as soon as his condition was discovered). The mother, who had been vaccinated 55 years before, had a mild attack of small-pox. The farmer, the son who was being visited, the farmer's daughter, the son's wife, and his child were attacked in succession. None of them had ever been vaccinated. All died from virulent small-pox except the child, who ultimately recovered at the cost of great disfigurement. These are all the cases in which vaccination is referred to, yet in the face of such evidence, recounted by himself, Surgeon-General Trask lends the weight of his authority as a high official of the United States Public Health and Marine Hospital Service, in a periodical which is widely circulated among lay as well as medical readers, to the assertion that it cannot be maintained that the protection afforded by vaccination is of general application.

SOME VIEWS ON NATIONAL INSURANCE AND TUBERCULOSIS.

A VERY important part of the National Insurance Bill is the proposal to devote some of the money to be raised by its operations, if it passes into law, to dealing with the important problem of the treatment and prevention of pulmonary tuberculosis among the persons affected by the Bill. Such an object must necessarily appeal most strongly to those interested in the medical and philanthropic aspects of the tuberculosis problem. We have received a copy of a collection of the opinions of some representative workers in both of these fields, which is published in the July number of the *British Journal of Tuberculosis*. Almost without exception the opinions expressed in regard to the proposals of the Chancellor of the Exchequer to set aside a capital sum of £1,500,000 to assist local charity and local authorities to build sanatoriums throughout the country and to provide a fund of £1,000,000 a year to maintain these institutions are commendatory, in some instances enthusiastically so. Mr. C. S. Loch, the secretary to the council of the London Charity Organisation Society, is, however, of opinion that there is most need for proper local dispensary and "contact" case work. He thinks that the Bill as it stands bids fair to kill off voluntary effort and believes that a much less ambitious scheme would be much more effective. The necessity of providing homes for advanced cases is strongly urged by Sir Thomas Oliver, Sir William J. Thompson, and Dr. Arthur Latham. The importance of the housing question in prevention is discussed by Sir Thomas Oliver and Dr. Duncan Forbes. Dr. G. F. McCleary objects strongly to the proposal to entrust the administration of the sanatorium benefits to the Local Health Committees rather than to the existing Public Health authorities. He suggests that what is required is the development and coördination of existing agencies and authorities, not the creation of new official machinery, which in his opinion is bound to lead to duplication of work, overlapping, and waste of effort. Sir Thomas Oliver, Mr. Waldorf Astor, Dr. Latham, and Dr. Duncan Forbes all emphasise the importance of the detection of early cases and the diffusion of knowledge in regard to this disease with this object in view. Dr. M. S. Paterson discusses the value of sanatoriums in the treatment of the disease and the use of specific methods of treatment. He also refers to the importance of preventive measures. Dr. Jane Walker insists that the constitution of the Local Health Committees shall be really representative, and that at least one-third of the members shall be women. Mr. David Davies, M.P., the chairman of the Welsh National Association for the Prevention and Abolition of Tuberculosis, expresses the opinion that the State grants should be made in some sort of proportion to local effort, and hopes that Wales may be treated as a unit for the purposes of sanatorium benefit. Several of the authorities express the hope that the tuberculosis dispensaries may share in the proposed benefits. While all are obviously convinced of the necessity for the proposed dealing with the tuberculosis problem, there is by no means unanimity of opinion as to the best means of utilising to the best advantage the money which it is proposed to raise. We feel strongly that existing institutions that are doing good and useful work should be encouraged and helped, and that provision should be made for the advanced cases, which are the greatest danger to the community at large and for which at present, apart from the Poor-law institutions, little provision exists. We also hope that if the proposed sums of money are forthcoming steps will be taken to ensure that the views of those having the closest and most intimate knowledge of the tuberculosis problem shall be duly considered, with a view to the most effective and economical employment of the money.

THE NASTIN TREATMENT OF LEPROSY.

AN important and highly interesting report,[1] by Dr. K. S. Wise, Government bacteriologist of British Guiana, has recently been issued by the Colonial Office on the treatment of leprosy by nastin. The report gives the results of the extended trial of this remedy in the Public Leper Asylum at Mahaica during the period from December, 1908, to September, 1910. What makes the report more interesting is the fact that Professor Deycke, the originator of this treatment, visited British Guiana at the end of 1908 at the invitation of the Governor, and with the approval of the Secretary of State for the Colonies, and remained in the colony for about six months in order that he might personally direct the method in which the treatment should be carried out. When he left his instructions were carefully observed and the treatment was maintained strictly on the lines he had indicated up to June, 1910, when experience suggested some modifications; among these was increase of the dose of nastin hypodermically injected; trial was also made of intramuscular injections, and single nodules were injected. In view of the apparent failure of nastin to cause any change or destruction in B. lepræ in the nasal cavities or in the larynx weekly or bi-weekly sprayings by means of an all-glass nebuliser were adopted. Intractable ulcerations were treated with ointments containing benzoylchloride in 2½ and 5 per cent. strengths. Finally, benzoylchloride in olive oil is now being used in some patients as an injection instead of nastin itself. These later methods have not been sufficiently long in use to warrant a report upon them being included in the present one, but it is hoped to give the results at a future date. So far as we know, although nastin has been

[1] A Report on the Nastin Treatment for Leprosy at the Mahaica Leper Asylum, British Guiana, 1908–10. By Dr. K. S. Wise, Government Bacteriologist. Presented to both Houses of Parliament by command of His Majesty, May 11th, 1911. Published by H.M. Stationery Office. Price 1s. 2d.

tried by many experts in the treatment of leprosy, in no instance that we remember has the test been applied before on so large and extended a scale. The reports on the former trials of nastin have been somewhat conflicting, some experts asserting that marked improvement followed the use of the remedy, while others of equal standing reported unfavourably upon it, saying that it had no apparent effect upon the disease at all. Nastin, our readers are reminded, was introduced by Professor Deycke, a German medical officer in the service of the Turkish Government, and stationed in Asia Minor, where he had opportunities of studying leprosy and its treatment. Nastin is a fatty principle extracted from cultures of a streptothrix which Professor Deycke found in the nodules of lepers. It is combined with benzoylchloride, and is made into ampoules with sterilised olive oil. It is now manufactured by a German firm of chemists at Biebrich, on the Rhine, for export. The action of this remedy is said to be effected by the nastin attaching itself to the leprosy bacillus, after which the benzoyl acts upon the bacillus, damaging it by the removal of its fat, when the normal fluids of the body complete its destruction. Nastin is used in three strengths—B_0, B_1, and B_2, the latter being the strongest. It was nastin B_2 which was employed throughout in British Guiana. The number of lepers treated by this remedy in the British Guiana Asylum during the period in question was 135, of whom 80 suffered from the nodular type of the disease, 24 from the anæsthetic, and 31 mixed. There was no selection of cases for the nastin treatment; any leprous patient asking for it received it. Few of the cases could be regarded as early, or favourable, instances; only 3·7 per cent. had had the disease to their knowledge for less than two years. It is worthy of mention that the majority of the lepers who received the injections declared that the treatment produced "a light feeling all over," and as a result they were observed to work harder and more willingly on the farm or on their own garden plots. It is not possible to say how much of this tonic effect was due to the remedy or to the renewed hopes of a cure inspired by the injections. Dr. Wise, in summing up the results, says that the experience gained at the Leper Asylum shows that a few early cases, that is, those of less than 18 months' duration, improved considerably under the nastin treatment, so much so, that they might be regarded approximately as cured. But, on the other hand, some early cases got very much worse, though treated precisely in the same way as the others. It does not seem possible to foretell which course a given patient will follow under the treatment until it has been in process for some time. The action of the nastin injections appeared to be that they initiated, accelerated, or intensified a natural process, which usually occurs spontaneously in too small a degree or too late in the course of the disease to be of any benefit to the patient. It is claimed by Professor Deycke that nastin is capable of producing reactions of a general or local kind, the latter being confined to leprous tissue. On this point Dr. Wise says that his experience does not enable him to give a definite opinion; he admits, however, that such reaction does occur in some cases. There seem to be great variations in individual susceptibility and resistance. Probably in the majority of cases large initial doses are required to produce reaction; moreover, immunity to the action of nastin seems to arise rapidly. As has already been pointed out, Professor Deycke claims that the injections cause definite changes to take place in the B. lepræ, which eventually lose their acid-fast property. In certain cases Dr. Wise found that there had been a marked and persistent increase in the bacillary changes which occur in every leprous patient in greater or less degree; in the majority of the cases treated by nastin a temporary increase of such changes was observed. In a number of instances, however, no increase of the usual natural bacillary changes was noted. Professor Deycke claims that the injections arrest the progress of the disease. But Dr. Wise says that some of the patients undoubtedly got worse under the treatment, while the majority remained *in statu quo ante;* a few improved, and three of them might be regarded approximately as cured. Dr. Wise's conclusion is that since the favourable results are so few, longer and wider experience can alone determine whether these successful cases were instances of natural improvement irrespective of the administration of nastin, or whether, on the other hand, the injections played an active part in effecting the disappearance of the leprotic deposits. We must confess that these results are disappointing, for we had been led to hope that the testing of the nastin treatment in British Guiana would yield definite and conclusive evidence of the correctness of Professor Deycke's contentions on behalf of his remedy for leprosy. It is possible that if there had been selection of "early" cases for treatment by nastin the tabular results might have appeared more favourable. In contrast to the cautious and guarded conclusions of Dr. Wise is the sanguine tone of the prefatory letter of the Governor of British Guiana to the Secretary of State which accompanies the report. In this the Governor says that since the nastin treatment has been introduced four lepers have been discharged, and he adds: "I am in a position to say that at the present time (March 31st, 1911) there are 56 cases in which no leprosy bacilli can be found, and of this number it is hoped that 75 per cent. will be fit to be discharged within the next three months. Never before in the history of the Leper Asylum of British Guiana has leprosy been successfully fought, and the results which have now been obtained will doubtless lead to further research and to a more complete conquest of this most terrible of diseases." We sincerely trust that there are substantial grounds for His Excellency's hopeful anticipations. It is possible that as his letter was written at a later date than Dr. Wise's report the Governor has been able to make use of certain information since obtained throwing a more favourable light on the treatment of leprosy. If this be the case, we hope that a further report will be published at an early date for the benefit of those who are concerned with the treatment of lepers, hitherto a hopeless task, and one from which little satisfaction could be derived.

THE DISINFECTION OF WOUNDS WITH TINCTURE OF IODINE.

IN a recent number of the *New York Journal of State Medicine* Dr. Charles F. Nieder discusses a subject that has, as our readers know, considerable interest for practical surgeons. The details given must be familiar to many of our readers, but iodine as a disinfectant is hardly sufficiently appreciated. Dr. Nieder has used tincture of iodine for disinfecting minor wounds and found it most satisfactory. He used it to prevent infection of slight abrasions of his own hands and found that these healed quickly. The inflammatory reaction which sometimes had occurred previously was almost invariably prevented. He uses the tincture in the treatment of nearly all minor wounds. The following are some examples. A boy stepped on a rusty nail which punctured the ball of the foot through to the dorsum. He was seen two days later with the wound infected and the foot badly swollen and very painful. A small incision was made on the dorsum and a fine ear curette was passed through the wound, cleaning out particles of dirt. A very narrow strip of gauze was twisted, dipped in tincture of iodine, and passed

through the wound. On the following day the pain and swelling had disappeared. The gauze was left in for another day and then removed. Recovery was rapid. In another case a boy had his palm badly lacerated by a bursting cartridge. The wound was cleaned, particles of wadding being removed from between and even from behind the metacarpal bones. The wound was swabbed out with tincture of iodine and rapid recovery ensued. In a third case a man sustained a bullet wound through the thickest part of the hand from the accidental discharge of a revolver whilst cleaning it. Particles of skin were removed from the wound at the point of entrance. Then a narrow strip of gauze saturated with tincture of iodine was passed through from the point of exit, between the metacarpal bones, and allowed to remain in for two days. It was then partly withdrawn, allowing the wound of exit to close, and on the following day was removed entirely. The patient returned to work five days after the accident. In a fourth case a bullet wound of the hand had been treated for three weeks by irrigation with hydrogen peroxide and packing with gauze. It was discharging pus freely from both entrance and exit. It was swabbed out with tincture of iodine. The pus rapidly disappeared and healing promptly took place. In applying iodine to large wounds care must be taken, as it is possible for sufficient to be absorbed to cause toxic symptoms. The chief objection to its use is the sharp burning sensation produced, but this lasts only a short time. Healing is much more rapid than under solutions of carbolic acid or bichloride of mercury. According to Dr. Nieder, punctured wounds caused by nails and similar objects should be enlarged in the skin, and cleaned out with a small ear curette; then a narrow strip of twisted gauze should be dipped in iodine, introduced, and allowed to remain in for two or three days. A strip should also be passed through bullet wounds of the extremities when the course can be followed with a probe. He advises also that in treating wounds requiring suture the skin along the edges should be painted with tincture of iodine, to prevent stitch abscesses.

THE LATE DR. JOSEPH F. PAYNE'S LIBRARY

THE valuable and extensive library of early medical, anatomical, and surgical works collected by the late Dr. Joseph Frank Payne, librarian to the Royal College of Physicians of London, was advertised for sale at Sotheby's, London, on Wednesday, July 12th, and two following days. It included many extremely rare works on the above subjects, besides what is probably the most complete collection in existence of books and tracts on plague, ranging from the "De Observatione in Pestilentia" of Alexander Benedictus of Verona (1493) and the "Tractatus de Epidemia" of Valastus de Tarenta (1497) to the "Treatise on Plague" of Dr. W. J. Simpson (1905). The whole were catalogued in 731 lots. Out of such a collection it must seem impossible to select anything for special mention, for without making the list unduly long whatever is selected may leave other volumes equally valuable to complain of omission. The discerning eye, however, will be struck with, among others, a MS. on paper of the "Trattato della Venena" of Petrus de Abano (fourteenth-fifteenth century); a very rare copy of the "Liber Mineralium" of Albertus Magnus; a very rare copy (1588) of Read's translation of the "Most Excellent and Compendious Method of Curing Woundes in the Head," of Franciscus Arceus, including Read's quaint poem, "A Complaint of the Abuse of the Noble Arte of Chirurgie"; a rare edition (1523) of the "Anatomy" of Berengarius Carpensis; the Florentine *editio princeps* (1478) of Celsus' "De Medicina," Lib. VIII.; the interesting anatomical studies of Realdus Columbus of Cremona, "De Re Anatomica," Lib. XV. (1559); and a first edition (1652) of Culpeper's "English Physitian." The various editions of Galen, Harvey, and Hippocrates are well represented, as is also the "Regimen Sanitatis Salerni." A note to the catalogue stated: "The whole will be offered first in one lot, but if the reserve price be not realised the collection will immediately be sold separately as catalogued." At 1 o'clock precisely on Wednesday the auctioneer mounted the rostrum, and at the upset price of £2000 invited biddings; these ceased at £2500, and the collection, "with all faults and errors of description if any," was knocked down to Mr. Tobin.

APPLICATION OF THE BIOLOGICAL SERUM TEST FOR BLOOD STAINS AT THE OLD BAILEY.

A RECENT case tried at the Old Bailey, in which a gardener named Pateman was convicted and sentenced to death for the murder of a girl to whom he had been engaged to be married, was an instance in which stains upon the clothing of the accused person had been proved to be human blood by the application of the biological serum test. On this occasion there was sufficient evidence apart from the blood stains to connect the prisoner with the crime, and the fact that he killed the woman was hardly in dispute, the defence being that he was insane when he committed the act. Mr. Justice Darling, however, called attention to the value of a discovery which enabled scientific evidence to be given proving the presence of human and not merely of mammalian blood, and also called attention to the fact that the evidence of Dr. W. H. Willcox connected the prisoner still more closely with the crime, as his examination pointed to the blood being that of an anæmic person, and the murdered girl had been proved to have been medically treated for anæmia.

THE FEEDING OF NECESSITOUS CHILDREN.

THE arrangements in connexion with feeding necessitous children at Brighton have been very successful, and education committees from various parts of England have visited them and gained some practical experience. Dr. Duncan Forbes and Dr. J. Lambert are to be congratulated upon the excellent results that have been obtained. Dealing firstly with the working of the canteens during the year 1910–11 the following shows at a glance the extent of the undertaking, and excepting it is necessary to add that the figures in parenthesis denote those for the year 1909–10, the table speaks for itself:—

Approximate number of children nominated for free meals (May–July)		400	
Approximate number of children nominated for free meals (October–April)		1,700	
Total free meals granted		76,701	(64,246)
Actual number of individual children who have received free meals:—			
Recommended by school medical officer	550		
Fed on economic grounds	446		
Fed for various reasons and not examined	54	1,050	(902)
Total number of 1*d.* dinners sold		3,679	(2,355)
Average number of free meals granted per day (May–July)		219	(250)
Average number of free meals granted per day (October–April)		491	(450)
Highest number to receive free meals in any one week		650	(700)
Total sum expended on food during the year		£246 10*s.* 10*d.*	(£216 9*s.* 6½*d.*)
Amount received for 1*d.* dinners		£15 6*s.* 7*d.*	(£10 11*s.* 10*d.*)
Cost of each meal		¾*d.* (4,5ths of 1*d.*)	
Total expenditure, including cost of feeding, administration, &c.		£379 14*s.* 2*d.*	(£453 10*s.* 3*d.*)

The large increase in the total number of free meals granted is accounted for by the fact that the number of days on which children were fed during the past year exceeded that of the previous year by 24 days, the numbers being 192 and 168 respectively. Now what is the result of all the work that

the compilation of these figures must have entailed? The reports submitted by Dr. Forbes and Dr. Lambert are encouraging. They show that the first gain an ill-nourished child makes on being properly fed is often in height. Dr. Lambert in tabular form gives an analysis of the recommendations made at the beginning and end of the session in the cases of 326 children examined at the commencement and at the end of the period of free meals. It is as follows:—

—	Boys.	Girls.	Total.
a. Recommended for free meals at beginning and end of session—i.e., nutrition not brought up to normal by feeding	66	75	141
b. Not recommended for free meals at beginning and end of session—i.e., nutrition not fallen below normal during feeding	61	71	132
c. Recommended for free meals at beginning and not recommended at end of session—i.e., nutrition brought above normal by feeding ...	19	19	38
d. Not recommended for free meals at beginning, but recommended at end of session—i.e., nutrition fallen below normal during feeding.	9	6	15
Total	155	171	326

Thus only 38 out of 326, or 11 per cent., received such benefit as to raise them out of the group which required extra feeding; while notwithstanding the free meals 15, or nearly 5 per cent., fell back into this group, although above the average at first. The drop, Dr. Lambert considers, might be due to three causes, probably the first and second being the most potent factors—namely, (1) disease; (2) insufficient or unsuitable food at home; (3) rapid increase of height, causing relative malnutrition—i.e., the weight not increasing so rapidly in proportion to the height as it should do. A table summarising the weight and height of 15 children in the above group (*d*) showed that although 10 out of 15 gained in weight the average gain was only 0·6 for 4–6 months' feeding, while the average gain in height was 3·2 cm., and as in Brighton nutrition is gauged by the relation of weight to height the tendency would be that all these cases would fall below the average standard of nutrition unless they were well above it at the first examination. It is not surprising, therefore, that with a greater gain in height than normal a great majority of the children remain ill-nourished according to the standard. However, it is quite clear from the results at Brighton that encouragement is given to continue the feeding of ill-fed school children, proving, as it does, that in such cases there is a rapid gain in height. Considerable gratification was expressed at the result of the year's working of the canteens during a recent meeting of the education authority, the hope being expressed that in such work of a national character the charge might later come from a national source instead of being contributed locally.

VISUAL EFFICIENCY.

THERE is a suggestive paper on this subject in the June number of the *Ophthalmoscope* by Mr. A. S. Percival. "A patient whose visual acuity has been reduced in both eyes from 1 to ·5 (i.e., from 6/6 to 6/12) has not suffered a loss of 50 per cent.; the vision that remains to him is much more important than the half that he has lost. The whole question resembles the well-known one in economics about the marginal value of a commodity." Such is the thesis of the paper, and Mr. Percival shows considerable ingenuity in deducing a mathematical formula, which will enable anyone to assign a numerical value to the loss of efficiency that results from the impairment of visual acuity in only one or in both eyes. The tables that he publishes should be of practical use to insurance companies, as giving a fair compensation to any person who insured his eyesight for say £100. It will be seen from the tables that such a policy-holder should receive the sum of £33 6*s.* 8*d.* if the vision of each eye were reduced to 6/12. Another form of policy is suggested by Mr. Percival in which account is taken not only of his loss of efficiency, but also of his loss in wage-earning capacity. A difficulty here arises as to the wage-earning capacity. For instance, we know of a coal hewer who was earning full wages when his visual acuity was less than 1/20, and yet other coal hewers seem to be totally disabled by having their acuity reduced to 6/36. The personal factor which is so important in these questions does not lend itself to mathematical treatment. At the same time, we recommend the careful study of Mr. Percival's paper to insurance companies, as it seems to us that the personal factor should be neglected by them, or they may be abused by malingerers.

THE TRANSPLANTATION OF LIVING BONE GRAFTS.

IN 1881 Jakimowitsch collected the theoretical arguments in favour of transplanting bony grafts, to repair defects in bone, and described very thoroughly the changes which certain forms of such grafts undergo when placed in an altered environment. Since then the literature on the subject has attained such dimensions that there exists a real need for further collation so as to enable the surgeon to draw conclusions from the mass of evidence scattered in the number of recorded cases. This work has recently been very ably performed by Streissler of Graz, who in presenting to the Berlin Surgical Congress the record of 29 of his own cases, devoted his attention to a thorough study of the subject, the result of which is seen in a lately printed monograph.[1] His own successes, as illustrated in the numerous diagrams and reproductions of X ray photographs included in this work, are too striking to be overlooked. They comprise not only the bridging over of small gaps in the flat and long bones, but much more interesting examples of the possibilities of the new methods as evidenced by the successful transplantation of a large portion of the tibia to repair a wide gap left after resection of the neck of the femur for cystic disease, and the equally successful restoration of the humerus by a piece of fibula 12 centimetres long taken from the same patient. Streissler insists on the advisability of using living bony tissue, preferably taken from the same patient, in the formation of these grafts. His experiments prove that living grafts taken from the lower animals, even when they contain both marrow and periosteum, are not desirable, since they tend to become absorbed and the periosteum cells appear to lose their proliferating power when transplanted. Dead grafts, either of decalcified bone, ivory, or artificial media, are quite unsuitable for the more severe cases, since their absorption is so rapid that they scarcely serve to form a support over which the periosteum of the grafted bone can grow. The transplantation of epiphyses, as advised by Helferich, has not so far proved of any great value, and Galeazzi has reported unfavourably upon it. Particularly valuable, from a practical point of view, is the author's extended discussion of the technique which has been found most useful in transplantation. A primary transplantation is the most useful, but in the majority of cases a secondary operation will have to be undertaken. The site of the implantation must be thoroughly opened up, care being taken not to damage the neighbouring tissues more than is absolutely necessary to enable the graft to be placed in position. To take the grafts from recently amputated but otherwise sound bones is seldom practicable, and stress is laid on the possibility, which does not seem to be merely theoretical, of

[1] Der gegenwartige Stand unserer klinischen Erfahrungen über die Transplantation lebender menschlichen Knochens, von Dr. Eduard Streissler, Assistant der Klinik, Graz, Separat-Abdruk aus Beiträge zur klinischen Chirurgie.

transmitting disease by this means. The writer therefore prefers to take his grafts from the patients themselves, usually from the tibia or fibula, both bones which are easily laid bare and from which the chiselling or resection of comparatively large pieces does not present any special difficulty. In obtaining a graft from the tibia, for example, the site of operation is carefully prepared for the reception of the graft, and the area over the bone whence it is proposed to remove the graft is as carefully sterilised with iodine solution, and the lower limb is rendered bloodless by means of a carefully adjusted Esmarch bandage. The manner in which the graft itself is removed and its size must depend largely on individual needs; a chisel or a Gigli saw is generally found to be the best instrument to use to detach the graft, which is then placed in normal saline solution, if the primary operation site has not yet been prepared, or is used at once. The implantation depends, again, largely on the requirements of the case. In some cases Streissler has found it possible to fix the ends of the graft firmly in the medullary cavity of the defective bony ends; in others he has had to use fixation methods such as wiring, aluminium or silver plating. The first method is much the more desirable one, and if the limb is subsequently immobilised by applying a well-fitting plaster support the results obtained are excellent. The wound at the site of the secondary operation heals easily, and gives no trouble in the majority of cases. That made for the implantation generally heals equally well if proper precautions are taken to keep it thoroughly aseptic. Indeed, Streissler lays justifiable stress on the prime importance of maintaining the most scrupulous asepsis in all transplantation operations. Unless that is seen to the grafts may necrose, be extruded as sequestra, or may give rise to prolonged suppuration which entirely nullifies the good obtained by the operation. The cases cited from the writer's own practice, and from the literature concerning 190 cases, are interesting examples of the complications which may arise when the aseptic technique has proved faulty. The indications for transplantation of living bone grafts are various. It has been used with success to repair defects in the long and flat bones, to lengthen a bone, to remedy deformity, in cases of arthrodesis and osteodesis, in fixing bones, and more recently in the transplantation of joints by Judet and Wrede. A full discussion of these indications, with illustrative cases, is given in the monograph. The results so far obtained go to show that the operation is one which has won for itself a recognised standing in surgery, and that should be more frequently employed than it is at present.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: NEW ADDITIONS TO THE MUSEUM.

A VALUED correspondent sends us the following additional note to our annotation in last week's issue, page 170, on the new additions to the Museum of the Royal College of Surgeons of England:—"Attention should be bestowed on a set of fœtuses, in early development, dehydrated and treated with caustic alkali so as to show the points of ossification opaque amidst transparent soft parts. Lionel Beale was probably the originator of this method, but Schultze reintroduced it in 1897, and Franklin P. Mall of Baltimore employed it scientifically in 1906. Mr. R. H. Burne, assistant conservator, made a series after Schultze's plan, in the course of the past year—preparations of great beauty. They are mounted in pure glycerine and deserve the attention of all anatomists and curators. It is especially important that Lionel Beale's claim to priority should be borne in mind by his countrymen, as Schultze himself admits it. In his communication, 'Ueber Verstellung und Conservirung durchsichtiger Embryonen zum Studium der Skeletbildung' (*Anatomischer Anzeiger*, vol. xii., 1897) he states that already as early as the year 1853 Beale, and later Theodor Koelliker, had employed similar reagents for the demonstration of points of ossification. Without doubt Schultze has introduced great improvements. The original specimen figured in Beale's 'Microscope in Medicine' lasted for 43 years, and then owing to an accident dried up and was spoilt. The re-arrangement of the pathological series, under Mr. Shattock and Mr. Cecil Beadles, is making great progress; the Museum is enriched by the acquisition of the collection of malformed pelves formerly belonging to the Obstetrical Society of London, and Dr. J. Davis Barris is engaged in taking measurements which will be indicated in print on the pelves when mounted. Mr. Doran is still engaged in the rearrangement and cataloguing of the obstetrical and gynæcological series. The all-inspiring energy of Professor A. Keith, the conservator, has played the chief part in the great progress made in the improvement and enlargement of the Museum of the Royal College of Surgeons so conspicuous of late years." We have much pleasure in endorsing our correspondent's estimate of Professor Keith's labours.

A GERMAN TUBERCULOSIS DISPENSARY.

IN the *Centralblatt für Allgemeine Gesundheitspflege*, Parts I. and II., 1911, there appears the "First Report of the Work of the Municipal Inquiry and Care Centre for Patients with Pulmonary Disease in Dortmund"—i.e., the tuberculosis dispensary of this town. As the procedure and methods differ in essential points from the Edinburgh system a short account may be interesting. The objects of the dispensary are summed up by the writer as a "seeking out of tuberculous disease in its hiding and breeding places by inquiries among families, and ensuring the earliest and most correct diagnosis by modern methods, looking after the housing and food of bacilli carriers who are in an advanced state of the disease, and assisting suspects and mild cases towards recovery by timely use of all available aids to that end, with special regard to prophylactic treatment in children; also coöperation with general practitioners, school doctors, and medical referees, with whom constant communication, both verbal and written, is maintained, coupled with strict supervision of all dispensary patients." The Dortmund Dispensary was started in January, 1908, and the chief sources of income are the municipality, the Westphalian Insurance Office, the Central Committee of Berlin, provident guilds, various manufacturing companies, and private subscriptions. Three rooms only were taken at first, and the management was placed in the hands of the administrative Poor-law officers and the city medical officer. The second assistant medical officer, who is also city bacteriologist, was appointed as attending physician. Two visiting nurses were also appointed. As at the Edinburgh Dispensary, there are consultations by the physician at regular hours, but only for diagnostic purposes, the patients' homes are visited, contacts are examined, and disinfection is performed by the municipal authorities free, but with a charge for carriage of articles to be disinfected of 4*s.* per journey. Patients found suffering from tuberculosis are classified, and suitable cases are sent to sanatoriums, convalescent homes, open-air schools, hospitals, or dispensaries, the various institutions and charities being chosen according to the needs of the patients. These may go direct to the dispensary or be sent by the visiting nurses or medical practitioners, the object being to obtain a diagnosis and advice. The officers and nurses of the dispensary do not undertake treatment. A cardinal point is that they must not interfere with the general practitioner, and no patient already under treatment is accepted unless he brings a note of recommendation from his medical adviser.

No clerical work is done by the nurses. After diagnosis of tuberculous disease the work of supervision is at once begun by the nurses; disinfectants, spit-pots, and advisory leaflets are given out, and if the patients are poor tickets are given for milk and food from the public kitchen; nothing in the shape of medicine is given, but considerable latitude in the distribution of food seems to be allowed. Beds are also let out on hire or lent free of charge—40 such are in use at present—and rooms at 4*s.* rent are hired where required for isolation of poor persons. If landlords have to forego keeping a lodger to make more room they are indemnified for this. All these benefits are made contingent on good behaviour and a strict adherence to the dispensary rules and regulations. When treatment is required patients are referred to the proper quarters, of which there is the usual choice—hospitals, dispensaries, and clubs. The following are some of the statistical figures from April 1st, 1909, till March 31st, 1910: Number of patients, 2025; physical examinations, 683; sputum examinations, 683; Pirquet tests, 291; visits of nurses, 2911; disinfections, 106. Besides a sanatorium, Dortmund has a "forest school" and a children's home. The importance of treating children in the suspected stage is always recognised. In the appendix there is a full statement of income and expenditure. For the above period the former was £740 and the expenditure £677, leaving a balance of £63. Among the items of expenditure the largest was for sending persons to sanatoriums, £302; nourishment, £74; for the two nurses, £95; and an honorarium for the medical officer of £37. The visiting nurses, like the medical officer, are not employed during the whole time by the dispensary, so that it is evident that the Dortmund administration differs in certain points from ours.

PARALYTIC HERPES OF THE CRANIAL NERVES.

SINCE the important researches of Dr. H. Head and Dr. A. Campbell on herpes zoster, the resemblance of that condition to what might be called posterior poliomyelitis, as opposed to the familiar anterior poliomyelitis, has been frequently pointed out. Recent work, more particularly of Dr. Ramsay Hunt of New York, has made it clear that the term might, with equal justification, be applied to zonas that involve cephalic regions. While it is true that the metameric arrangement so characteristic of spinal nerves cannot be demonstrated readily in the case of the cranial nerves, yet the analogy between the ganglia on the posterior spinal roots and those of the cranial nerves is well known. On the fifth nerve there is the Gasserian ganglion, on the nervus intermedius of Wrisberg the geniculate; the ganglia of Andersch and Ehenritter correspond to the ninth or glosso-pharyngeal, the jugular and plexiform to the tenth. Their cells are unipolar and are the nuclei of origin of their respective sensory nerves. The topography of these various nerve distributions is complex, but is being definitely established both by clinical and by experimental research. The main distribution of the fifth is familiar, and of the second and third cervical: between these is an area involving the region round the ear which is supplied by the nervus intermedius, glosso-pharyngeal, and vagus. The geniculate ganglion supplies the concha, tip of the anti-tragus, part of the anti-helix and its fossa; the ninth and tenth supply the posterior portion of the tympanum and external auditory meatus, part of the posterior internal surface of the pinna, and the adjacent mastoid region. The fifth supplies the rest of the tympanum and external auditory meatus. By observing minutely the distribution of the herpetic vesicles it can be determined which nerve or nerves are involved. In *La Presse Médicale* of May 27th Dr. Henri Claude and Dr. H. Schaeffer have published a new case of "posterior poliomyelitis" of the cranial nerves which presents several features of interest. The patient was a young woman of 28, with a characteristic history of malaise, headache, and pain, who displayed a widespread herpes on the left side of the face, head, and neck. Not only were the sensory cranial nerves, fifth, eighth, ninth, and tenth, involved, but in addition there were motor phenomena in the distribution of the third and sixth, motor fifth, and seventh. A careful investigation of the site of the herpetic vesicles showed that the area supplied by the nervus intermedius had escaped. Tinnitus and hypoacousis suggested implication of the spiral ganglion. The explanation of the paralysis of certain motor nerves is more difficult, but the writers incline to the theory of a basilar meningitis, especially since lumbar puncture revealed the presence of a profound meningeal reaction.

THE NEED OF PROPER SANITARY ADMINISTRATION IN EGYPT.

GENERAL regret will be felt at the death of Sir Eldon Gorst, His Majesty's Agent and Consul-General for Egypt. It has occurred, moreover, at a critical time, and in more directions than one his successor will have an arduous task, while as far as sanitary matters are concerned he may have to face a certain amount of inherited responsibility. Especially do we note with some anxiety a recrudescence of plague in Egypt, concerning which we published a letter from a correspondent in our issue of July 8th. Attention was therein called to the fact that plague figures had more than doubled during the first half of 1911, as compared with the corresponding period of 1910. We now find our correspondent's statements confirmed on the spot by an article in the *Egyptian Gazette* of June 27th, which has just reached us. From that article we learn that, according to the last official bulletins, there were 684 cases more in the first half of 1911 than in the same period of last year, and nearly three times as many as in the whole year of 1909, the increase occurring principally in Upper Egypt. As for Lower Egypt, while only 27 cases with 9 deaths are recorded for Alexandria during the half year, it is pointed out that the greater number of these cases have occurred recently. During the week ending June 17th 25 fresh cases of plague developed. The *Egyptian Gazette* complains of the lack of sanitary organisation—bearing out our correspondent's plea for enforcing on the fellaheen certain "necessary precautions and cleansings." Two years ago,[1] in reviewing the second annual report of Sir Eldon Gorst on the progress made in the various departments of the Egyptian Government, we expressed our regret that the prevention of disease was practically ignored therein, and that in its brief observations on the public health reference was made exclusively to the cure of maladies already contracted, none whatever being made to the adoption of sanitary measures properly so-called. It seems probable that the failure to wage successful warfare against plague is due to the recent developments in the government of the country, and medical men will welcome for the public good the hand of a strong administrator as far as sanitary needs are concerned. They may feel confident that Lord Kitchener's *régime* will be begun in full apprehension of the existing difficulties.

THE TREATMENT OF ARTHRITIS DEFORMANS.

Dr. P. W. Nathan of New York has published a series of papers dealing with the etiology and classification of the various morbid conditions of the joints which are usually included, often without much discrimination, within the terms "osteo-arthritis," "rheumatoid arthritis," and "arthritis deformans." He separates all these diseases into two main

[1] THE LANCET, June 19th, 1909, p. 1775.

groups—the inflammations and the degenerations. One large and important section of his degenerative group is that to which he gives the name "metabolic osteo-arthritis." This group includes cases belonging to that type of arthritis in which joints are affected symmetrically and at the periphery first; it is always polyarticular and progressive, leading finally to muscular contraction and deformity. Examination with the X rays shows rarefaction at the ends of the bones the joints of which are implicated. The name given to this group by Dr. Nathan, as also his plan of treatment, is based on the belief that the disease is a degeneration which has its origin in general metabolic and nutritional disturbance. The plan of treatment which he advocates[1] is divided into two stages. In the first stage, which is prolonged until the disease has become quiescent, the patient is kept at rest and receives a nutritious diet with doses of thymus extract. When the disease has become arrested a very gradual return to active use of the affected limbs is begun; intractable deformities are corrected by tenotomy or even osteotomy if need be. The two chief points in this plan of treatment are the administration of thymus extract and the enforcement of absolute rest until the disease has ceased to make progress. Dr. Nathan was first led to try thymus extract by reading of its effects on skeletal development in Basch's experiments; he uses tablets of 5 grains each, giving from two to four three times daily either before or after meals. It must be given continuously for a long period—in some cases for months. Dr. Nathan does not regard thymus extract as a specific, but he claims that his results in the treatment of 186 cases by this method prove that if it is conscientiously taken for a long time, the patient being managed judiciously meanwhile, marked improvement, if not perfect cure, can always be expected. He says that of 18 patients who were helpless and bedridden, eight are walking without stick or crutch and have no pain, and his figures suggest that failure is to be expected in quite a small percentage even of the severer cases. At any rate, he makes out a case for trial of his method.

THE BRITISH SECTION AT THE DRESDEN INTERNATIONAL HYGIENE EXHIBITION.

AFTER overcoming almost insuperable difficulties the British committee has succeeded in equipping a British section at the International Hygiene Exhibition in Dresden. As we have already stated, the section was opened on June 29th, Professor Renk, the vice-president of the exhibition, representing the administration, and Mr. H. W. Armit the British committee. Among those who were present mention should be made of Dr. J. Honsberger, the delegate of the Canadian Government, Dr. J. A. Murray and Dr. W. H. Woglom of the Imperial Cancer Research Fund, and Dr. W. Yorke of the Liverpool School of Tropical Medicine. The British Legation was represented by Mr. Cardall, and the Consulate by Mr. Bassange. Among the illustrious guests were the delegates of the King of Saxony and of the Saxon Government, the Lord Mayor of Dresden, and many diplomatists. The speeches were brief and only two in number, Mr. Armit offering a welcome to the guests of the committee and Professor Renk responding.

The section has been planned on scientific lines and is distinctly technical. Daily demonstrations, however, will be held which will render the significance of the exhibits intelligible to the masses. The sections consist of the Care of Infants, the Care of the Defective, School Hygiene, Dental School Hygiene, Physical Training, the Control of Food, the Diseases Communicable from Beast to Man, the Diseases chiefly Affecting Man, Tropical Diseases, Cancer Research, the Control of Infectious Diseases, Ambulance and Rescue Work in Mines, &c., the Care of the Sick at Home and also in India and China, Poisons in Food, Industrial Poisoning and Dangerous Trades, Cremation, Housing and Town-planning, Disposal of Sewage and Effluents, Water-supply, Smoke Abatement, and Military Hygiene and General Hygiene.
